SKF – the knowledge engineering company

From one simple but inspired solution to a misalignment problem in a textile mill in Sweden, and fifteen employees in 1907, SKF has grown to become a global industrial knowledge leader.

Over the years, we have built on our expertise in bearings, extending it to seals, mechatronics, services and lubrication systems. Our knowledge network includes 46 000 employees, 15 000 distributor partners, offices in more than 130 countries, and a growing number of SKF Solution Factory sites around the world.

Research and development

We have hands-on experience in over forty industries based on our employees' knowledge of real life conditions. In addition, our world-leading experts and university partners pioneer advanced theoretical research and development in areas including tribology, condition monitoring, asset management and bearing life theory. Our ongoing commitment to research and development helps us keep our customers at the forefront of their industries.

Meeting the toughest challenges

Our network of knowledge and experience, along with our understanding of how our core technologies can be combined, helps us create innovative solutions that meet the toughest of challenges. We work closely with our customers throughout the asset life cycle, helping them to profitably and responsibly grow their businesses.

Working for a sustainable future

Since 2005, SKF has worked to reduce the negative environmental impact from our operations and those of our suppliers. Our continuing technology development resulted in the introduction of the SKF BeyondZero portfolio of products and services which improve efficiency and reduce energy losses, as well as enable new technologies harnessing wind, solar and ocean power. This combined approach helps reduce the environmental impact both in our operations and our customers' operations.

SKF Solution Factory makes SKF knowledge and manufacturing expertise available locally to provide unique solutions and services to our customers.

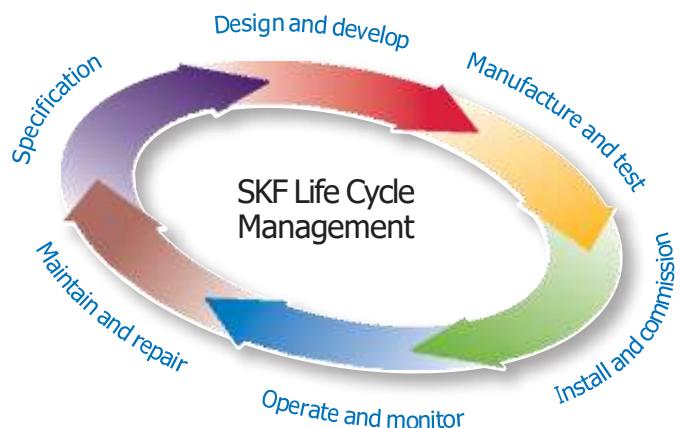

Working with SKF IT and logistics systems and application experts, SKF Authorized Distributors deliver a valuable mix of product and application knowledge to customers worldwide.

Our knowledge – your success

SKF Life Cycle Management is how we combine our technology platforms and advanced services, and apply them at each stage of the asset life cycle, to help our customers to be more successful, sustainable and profitable.

Working closely with you

Our objective is to help our customers improve productivity, minimize maintenance, achieve higher energy and resource efficiency, and optimize designs for long service life and reliability.

Innovative solutions

Whether the application is linear or rotary or a combination, SKF engineers can work with you at each stage of the asset life cycle to improve machine performance by looking at the entire application. This approach doesn't just focus on individual components like bearings or seals. It looks at the whole application to see how each component interacts with each other.

Design optimization and verification

SKF can work with you to optimize current or new designs with proprietary 3-D modelling software that can also be used as a virtual test rig to confirm the integrity of the design.

Bearings

SKF is the world leader in the design, development and manufacture of high performance rolling bearings, plain bearings, bearing units and housings.

Machinery maintenance

Condition monitoring technologies and maintenance services from SKF can help minimize unplanned downtime, improve operational efficiency and reduce maintenance costs.

Sealing solutions

SKF offers standard seals and custom engineered sealing solutions to increase uptime, improve machine reliability, reduce friction and power losses, and extend lubricant life.

Mechtronics

SKF fly-by-wire systems for aircraft and drive-by-wire systems for off-road, agricultural and forklift applications replace heavy, grease or oil consuming mechanical and hydraulic systems.

Lubrication solutions

From specialized lubricants to state-of-the-art lubrication systems and lubrication management services, lubrication solutions from SKF can help to reduce lubrication related downtime and lubricant consumption.

Actuation and motion control

With a wide assortment of products – from actuators and ball screws to profile rail guides – SKF can work with you to solve your most pressing linear system challenges.

1 General information

1.1 Introduction

As the world's leading rolling bearing manufacturer, SKF supplies practically every type of bearing for rotational and linear motion. SKF is therefore in a position, both technically and economically, to meet almost any customer requirement.

This catalogue covers the entire range of SKF precision rail guides and accessories. SKF precision rail guides are highly accurate products for linear motion and are ideally suited for use in a wide variety of machine tools, machining centres, handling systems and special machinery, as well as in measuring and testing equipment and semi-conductor production machines.

SKF precision rail guides are available in many different designs, sizes and standard lengths and which incorporate ball, roller or needle roller assemblies and slide coatings. They are supplied with the required accessories for attachment and sealing. The use of SKF precision rail guides enables the construction of economical, clearance-free linear guides of almost any type and length, according to the building block principle.

The characteristics of the precision rail guides include:

- A constant, high degree of running accuracy.
- Low-friction, stick-slip free operation.
- High speed of travel.
- Low heat generation.
- Low wear and high reliability.
- High rigidity.
- Excellent load carrying capacity.

If cage creeping is likely, in particular when the guide is mounted vertically, precision rail guides with anti-creeping systems (ACS) are an obvious choice, as they will eliminate this problem. They are available for nearly all types of rolling elements.

For applications characterised by high accelerations or short strokes of high frequency, SKF rail guides with slide coating are recommended. These rail guides are also suitable for machine tool applications where the damping properties of the guides are of greater importance than is the lower friction of rolling element rail guides. For those applications where precision rail guides are unsuitable, for instance because of their limited travel, SKF can supply alternative forms of linear guidance systems, like profile rail guides or linear ball bearings.

All fast-selling precision rail guides are also available in convenient kit packaging. This ensures the complete delivery of all components including end pieces and screws in one package from stock.

This catalogue brings together all the basic data that we believe will be of interest to customers. For further specialised advice, please contact your nearest SKF sales office.

1.2 Features and benefits

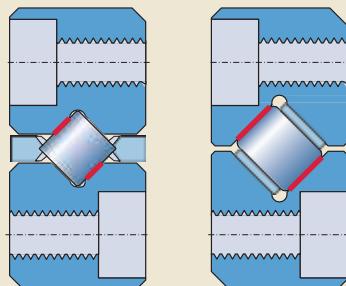

Cage creep test results

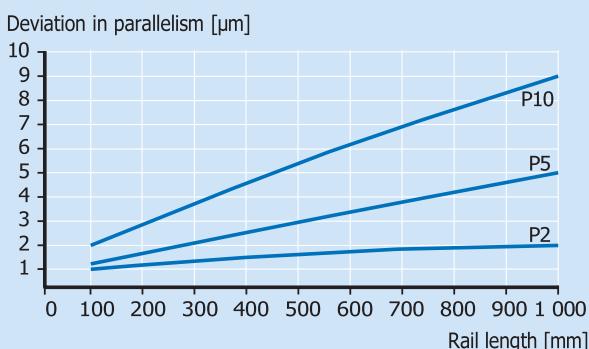

Anti-creeping system

SKF developed the industry's first anti-cage-creep solution. It keeps the movement of the cage in the required position at the loaded zone, avoids cage creep from high operational speed and acceleration to uneven load distribution and weak adjacent parts, and prevents unplanned downtime and additional maintenance.

In addition, due to defined cage position, SKF precision rail guides with anti-creeping system, or ACS, enable increased accuracy, higher accelerations (tested up to 160 m/s²), and reliable vertical installation.

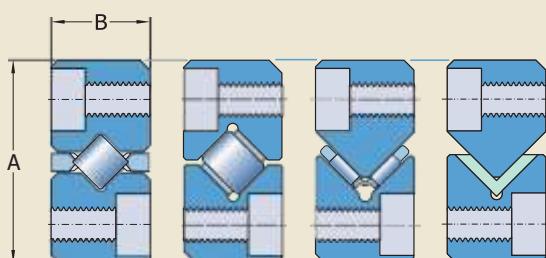

Permissible deviation in parallelism between reference surfaces and raceways

Extreme accuracy and positioning repeatability

Compared to other linear guiding products, precision rail guides provide the highest linear guiding accuracy. Precision rail guides from SKF are available in three different precision classes to meet a range of requirements for precision. The increased accuracy and repeatability enables higher productivity and product quality in diverse applications, e.g. semi-conductors, machine tools, measurement and testing equipment, and medical equipment.

Modular range

With the SKF modular range of precision rail guides, outer rail dimensions remain the same, but rolling elements are interchangeable to best meet application demands. With this design modularity, customers can easily increase load rating or extend rating life without having to redesign the equipment. The SKF modular range of precision rail guides covers 80% of dimensions on the market. Additionally, the customer can choose between ball assemblies, crossed roller assemblies, crossed roller assemblies with ACS/ACSM, needle roller assemblies and slide coatings.

1.3 Product overview

SKF can offer a large assortment of precision rail guides ([+ fig. 1](#)). The different versions, mainly characterized by their type of rolling elements, are as follows:

- Ball assemblies of LWRB series.
- Ball assemblies with Anti-Creeping System of LWRB ACSM series.
- Crossed roller assemblies of standard LWR series.
- Crossed roller assemblies of optimised LWRE series.
- Crossed roller assemblies with Anti-Creeping System of LWRE ACS series.
- Crossed roller assemblies with Anti-Creeping System of LWRE ACSM series.
- Needle roller assemblies of LWRM/LWRV series.
- Needle roller assemblies of LWM/LWV series.
- Needle roller assemblies with Anti-Creeping System of LWM/LWV ACSZ series.
- Slide coating of LWRPM/LWRPV series.

The following table shows the complete range of SKF precision rail guides, together with all available sizes. The blue shaded areas indicate the sizes included in the Modular Range. Contrary to the current lack of uniformity within the market, the interchangeable precision rail guides of the Modular Range are all within the same outer dimen-

sions ([+ fig. 1](#)). For fast delivery, please refer to the rail guides that are available in kit packaging.

1.4 ACS in general

Many users are familiar with "cage-creeping" in conventional precision rail guides. This occurs when the cage moves out of its intended position, adversely affecting performance and possibly requiring service. This effect may occur, for example, as a result of high acceleration, uneven load distribution or vertical mounting. SKF has solved this problem by offering highly sophisticated Anti-Creeping Systems (ACS) for most guiding types.

Advantages:

- Cage-creeping eliminated.
- Suitable for high acceleration, vertical mounting and uneven load distribution.
- Increased accuracy due to defined position of the cage.
- Easily interchangeable with standard precision rail guides because they have identical dimensions.
- Less downtime and maintenance.

LWRE with ACS

The original anti-creeping system for all types of LWRE rail guides.

LWRE with ACSM

Refinement of our own ACS solution led to version ACSM for LWRE rail guides with a maximum length of 400 mm. The cage, with an involute-toothed control gear made of brass, and involute teeth directly machined into the rail, are especially suitable for high accelerations.

LWM / LWW with ACSZ

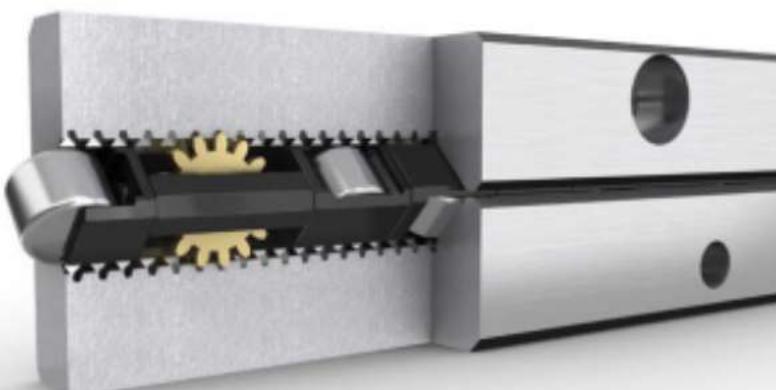

For precision rail guides with needle roller cages, SKF can offer version ACSZ.

Both rails are equipped with gear racks made of steel. The cage carries two steel control gears that help to ensure the correct cage position.

LWRE with ACS

LWRE with ACSM

LWM / LWW with ACSZ

Fig. 2

Rails for anti-creeping cages

Rails for ACS- or ACSZ-cages can be designed for a specified stroke or maximum stroke, with the length of the toothing in the rail varied accordingly († fig. 2 and 3). Rails for ACSM-cages are always made for maximum stroke.

A rail for maximum stroke has teeth along its entire length. This may be required for mounting, maintenance or dismounting purposes. Rails for ACS- or ACSZ-cages are delivered with maximum stroke as standard and no special ordering code is required. For rails with a specified stroke, the length of the stroke, which is symmetrical to the rail, must be stated in millimetres after the suffix ACS / ACSZ. ACS- and ACSZ-cages must be operated only along the specified stroke length to ensure that the control gear is not damaged.

Ordering example – maximum stroke:

4x LWRE 6500 ACS
2x LWAKE 6x30 ACS
8x LWERE 6

Ordering example – specified stroke of 340 mm:

4x LWRE 6500 ACS 340
2x LWAKE 6x30 ACS
8x LWERE 6

Ordering example – kit packaging:

LWRE 6200 ACSM-KIT

LWRE ACS standard stroke

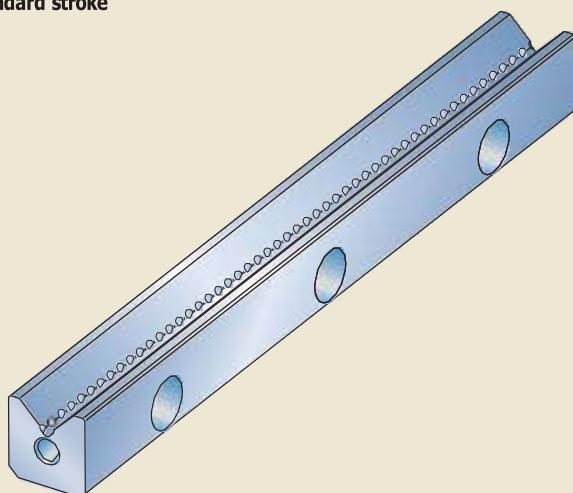

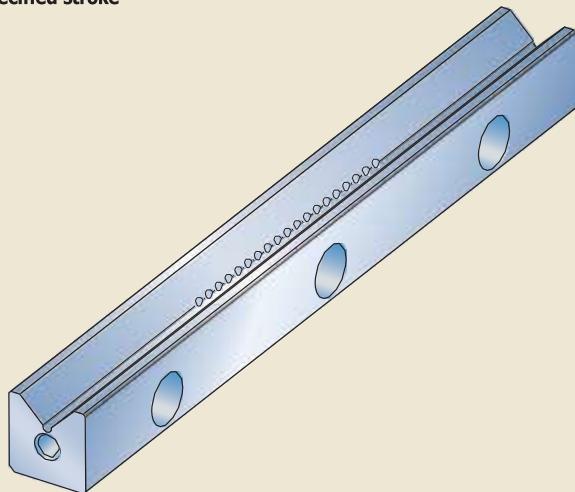

Fig. 3

LWRE ACS specified stroke

1.5 SKF precision rail guides in kit packaging

To simplify the ordering process and warehousing for our customers, SKF offers precision rail guides in pre-defined kits. Each kit consists of 4 rails in precision class P10, 2 cages and 8 end pieces (ACSM kits without end pieces). The available kits can be found in the specific rail guide chapters. On request it is possible to order a kit with two rails in standard length and two short rails with lead in radius. Additionally the number of rolling elements can be varied, see ordering code.

Completely customised precision rail guide sets are also possible on request.

Advantages of rail guide kits

- All components required are supplied ready-to-mount and can be ordered with a single order number.
- Most kits are available from stock.
- Cage length is easily adjustable.¹⁾
- Load capacities are already calculated for the kit.²⁾
- Available with ACS or ACSM for effective prevention of cage-creeping.
- Rails for ACS- or ACSM-cages with tooth-ing along entire length (rails for maximum stroke).

¹⁾ Do not cut the cage shorter than 2/3 of the total rail length.

²⁾ Load capacities are given for a kit of 4 rails and 2 cages in clamped arrangement (C_{eff} slide, C_{eff} slide)

1.6 Technical data

1.6.1 Materials

As standard, precision rails are manufactured from tool steel 90MnCrV8 (1.2842) with a hardness between 58 and 62 HRC. However, if required by the application, the rails can also be supplied in stainless steel, e.g. X90CrMoV18 (1.4112). All rails from the LWRE ACSM series are made of stainless steel X46Cr13 (1.4034) or X65Cr13 (1.4037).

Standard rolling elements are made from carbon chromium steel 100Cr6 (1.3505) with a hardness between 58 and 65 HRC. Stainless steel rolling elements are available on request.

The cages of SKF rolling element assemblies are manufactured from hard plastic or aluminium. The material of LWAKE crossed roller units is POM, and for all other rolling element assemblies, PA 12 or equivalent, sometimes reinforced with glass fibres. Aluminium cages are made of AlMgSi0,5 (EN AW-6060). For other cage materials such as Peek, steel, brass, etc., please contact SKF.

Standard end pieces are made of blackened steel. Additionally, the standard end pieces can be supplied as chromed end pieces when ordered with suffix "/HV".

1.6.2 Coating

For corrosive environments, the rails can be protected with a special TDC (Thin Dense Chrome) coating. This coating, with a layer hardness of 900 to 1300 HV, substantially improves corrosion resistance and thus increases wear resistance under critical operating conditions. The salt spray test, which complies with DIN EN ISO 9227, resulted in 72h corrosion protection. The coating is matt grey in colour and complies with RoHs requirements. The load capacity is not affected by the coating. Due to the electrolytic process, the mounting holes and other grooves or drills might not be fully coated. The suffix for ordering is "/ HD".

1.6.3 Permissible operating temperatures

The range of operating temperature for SKF precision rail guides depends largely on the particular cage type used. Guides with metal cages and end pieces without wipers can generally be used up to +120 °C. For rail guides with plastic components, the operating temperature range is -30 °C to +80 °C. Please note that the temperature limit of the used lubricant must also be taken into account.

Permanently higher operating temperatures for precision rail guides without plastic components are possible but the hardness of the material and thus the load carrying capacity will decrease. The detailed explanation of the influence of higher temperatures on the load carrying capacity (factor f_t) can be found in chapter 1.8.3. The accuracy of the rail guide worsens with increasing temperature due to changes in the material structure and dimensional changes.

1.6.4 Permissible speed and acceleration

SKF precision rail guides that are correctly mounted and preloaded, can be used for running speeds up to 2 m/s and accelerations up to 25 m/s². Needle roller cages can be accelerated with maximum 100 m/s². For cages with ACSM, the maximum acceleration is 160 m/s² and for cages with ACSZ the value is 100 m/s². Higher running speeds and accelerations are possible, depending on bearing design, bearing size, applied load, lubricant and bearing preload. In such instances, please consult SKF.

1.6.5 Permissible minimum load

To prevent the rolling elements from sliding on the raceway during operation at higher speeds or high acceleration, the precision rail guide system must be loaded at all times with a minimum 2% of the dynamic load rating. This is particularly important for applications characterized by highly dynamic cycles. Precision rail guide systems preloaded according to the table, *Tightening torques of set screws* († chapter 3.1.10), are typically able to satisfy the stated minimum load requirements.

1.6.6 Permissible maximum load

ISO 14728 Part 1 stipulates that calculation of bearing life is valid only when the equivalent dynamic mean load P_m of a precision rail guide does not exceed 50% of the dynamic load rating C . Any higher loading leads to an imbalance of stress distribution, which can have a negative impact on bearing life. As stated in ISO 14728 Part 2, the maximum load should not exceed 50% of the static load rating C_0 .

1.6.7 Friction

Friction in a precision rail guide with rolling elements depends not only on the loading, but on a number of other factors, notably the type and size of the bearing, the operating speed, and the properties of the lubricant. The cumulative running resistance of a rail guide is composed of the rolling and sliding friction at the contact zone of the rolling elements, friction at the points of sliding contact between the rolling elements and cage, churning work within the lubricant and friction from the seals or wipers.

The coefficients of friction under normal operating conditions, with grease lubrication and good mounting accuracy, are between 0,0005 and 0,004. For rail guides fitted with wipers, the coefficient of friction and the starting friction is significantly higher due to the friction of the wipers themselves.

1.6.8 General rigidity behaviour

The rigidity of a precision rail guide (expressed in N/μm) is defined as the ratio between the acting external load and the elastic deflection resulting in the rail guide. Besides the load carrying capacity, rigidity is one of the most important selection criteria for a precision rail guide system. The elastic deflection of a system depends on the magnitude and direction of the external load, the preload, the type of rail guide including size and cage length, and the mechanical properties of the adjacent support structure, including screws and joints between components. On a preloaded rail guide system the deflection under load within a given load range will be less than for a rail guide without preload. Variations in contact geometry are the main factors contributing to the general rigidity behaviour of the cage types († diagram 3). The details are explained in chapter 1.11.

1.6.9 Precision classes of rails

In order to meet the precision requirements of rail guide systems, SKF produces rails in three different precision classes. These are classified according to the parallelism between the raceways and reference surfaces A, (as indicated, on the reverse side of the SKF label), and B. See **table 2** and **fig. 4**.

Table 2

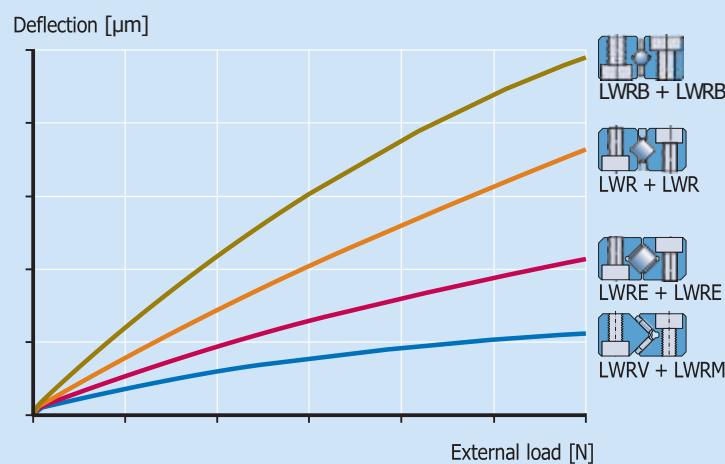

Tolerance t of parallelism to reference surfaces

Rail length mm		Precision class		
	>	P10	P5	P2
	≤			
0	100	2	1	1
100	200	3	2	1
200	300	4	2	1
300	400	5	2	2
400	500	6	3	2
500	600	6	3	2
600	700	7	4	2
700	800	8	4	2
800	900	8	5	2
900	1 000	9	5	2
1 000	1 200	10	6	3
1 200	1 400	11	6	3
1 400	1 600 ¹⁾	12	7	3

¹⁾ Rail length > 1 600 mm, please contact SKF

Diagram 3

General rigidity behaviour of different rolling elements

P10

This is the standard precision class and meets the requirements of general machinery. The tolerance of parallelism for a 1 000 mm long rail is maximum 9 μm.

P5

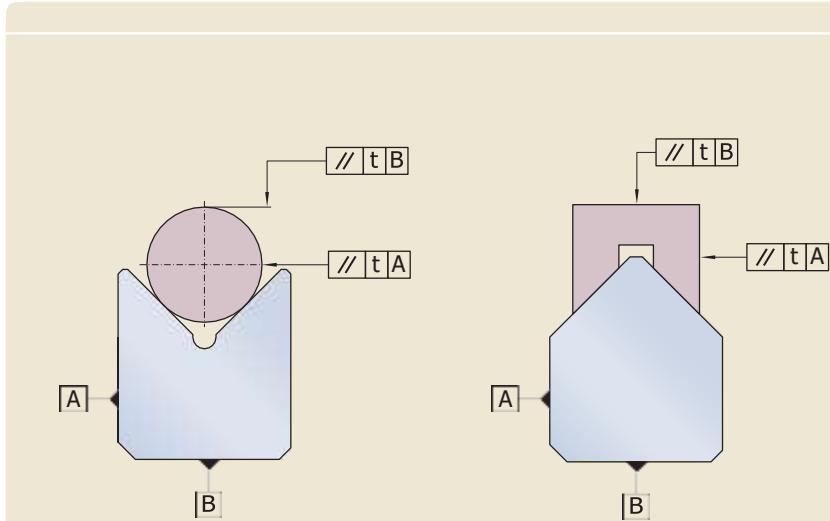

Precision class P5 satisfies the demands normally made on the running accuracy for machine tool applications. The tolerance of parallelism for a 1 000 mm long rail is 5 μm maximum.

P2

Precision class P2 is for the most exacting demands. Rails made to this precision class should only be used when the associated components are manufactured to a correspondingly high degree of precision. Rails of precision class P2 will be manufactured by SKF to special order.

If the requisite accuracy on the order is not specified, rails with standard P10 tolerances will be supplied.

Fig. 4

1.6.10 Precision of rolling elements

The rolling elements used in precision rail guide cages are of very high quality and have a specification according to **table 3**. Besides the standard type, needle roller cages can be delivered in class G1, when ordered with suffix /G1.

Table 3

Precision of rolling elements					
Rolling element	Norm	Class	Roundness	Sorting	Comment
—	—	—	μm	μm	—
Balls	DIN 5401-1	G10	0,25	1	Standard
Cylinder roller	DIN 5402-1	G1	0,5	1	Standard
Needle roller	DIN 5402-3 Not mentioned in DIN	G2 G1	1 0,5	2 1	Standard Suffix /G1

1.6.11 Dimensional accuracy

SKF precision rail guides are produced with the following tolerances (**† fig 5**):

Width A: $+0 / -0,3$ mm
 Height B: $+0 / -0,2$ mm
 Centre Height H1 = H2: $\pm 5 \mu\text{m}$ ¹⁾
 Assembly Height T = H1 + H2: $\pm 10 \mu\text{m}$ ¹⁾

Rail length L_{rail}:

$L_{\text{rail}} \leq 300$: $\pm 0,3$ mm
 $L_{\text{rail}} > 300$: $\pm 0,001 \text{ mm} \cdot \frac{1}{L_{\text{rail}}}$

1.6.12 Grading

For the typical “clamped” arrangement, four precision rail guides are needed. To reach the best performance in terms of lifetime, rigidity and running behaviour, it is important that the centre height of the four rails is within a small tolerance. This is the reason why SKF rails are graded and packed together according following rules:

Rails for crossed roller or ball cages:

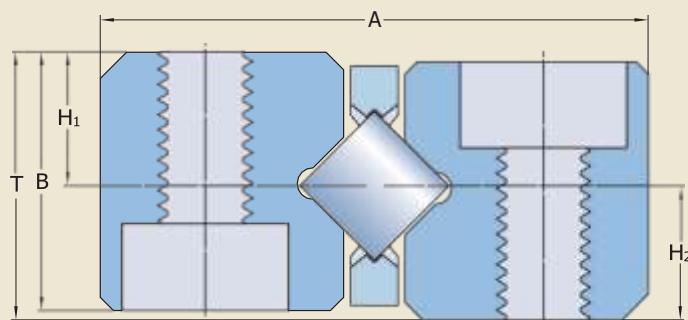

Four rails are matched to each other and packaged as a set.

Rails for needle roller cages or slide coatings:

Two M shaped and two V shaped rails are matched and packaged as pairs.

Because of the very close standard tolerance of the centre height, it would also be possible to pair any rail for a standard application (precision class P10) if necessary.

Fig. 5

¹⁾ for rail length $L_{\text{rail}} < 1\,000$ mm

1.6.13 Jointed rails

Jointed rails are always graded and well-sorted by SKF to ensure smooth running. They are delivered with markings as indicated in **fig. 6**. For rails composed of two or more sections, the tolerance for the total length is ± 2 mm.

Fig. 6

--------	--------	--------	--------

1.7 Dimensioning of precision rail guide systems

Often it is not possible to build a prototype machine just to find out which the most suitable guiding for a given application is. Instead, the following established and proven procedures are recommended:

- Calculation of rating life
- Calculation of static safety factor

These two calculation methods must consider all loads and forces acting on the precision rail guide system. Representatives of the acting bearing load that describe the whole load case are needed. These representatives must combine all forces, leverarms and torque loads, which can vary by time or stroke (*† chapter 1.9* and following). The rating life of a precision rail guide with rolling elements is defined as the total linear distance travelled by the rails before the first sign of material fatigue occurs on one of the raceways and/or the rolling elements. For the selection of rail guides based on rating life calculation (*† chapter 1.7.3*), the dynamic load rating C , as defined in *chapter 1.8*, is used. It is expressed as the load that results in a bearing life of 100 000 m.

1.7.1 The concept of static safety factor calculation

When selecting a precision rail guide, the static safety factor calculation must be considered when one of the following cases arises:

- The bearing operates under load at very low speeds.
- The bearing operates at normal conditions but must also accept heavy shock loads.
- The bearing is loaded stationary for long periods of time.
- The bearing is loaded with $P > 50\%$ of the dynamic load rating C where the theory of rating life calculation is not valid any more.

In all such cases, the permissible load is determined not through material fatigue but through the permanent physical deformation at the contact zone of the rolling elements and raceways. Load applied when stationary or at very low operating speeds, as well as

heavy shock loads, causes flattening of the rolling elements and results in damage to the raceways. The damage may be uneven or may be spaced along the raceway at intervals corresponding to the rolling element separation. This permanent deformation leads to vibration in the bearing, noisy running and increased friction and even may cause a decrease in preload and, in an advanced stage, an increase in clearance. With continued operation, this permanent deformation may become a starting point for fatigue damage due to resulting peak loads. The seriousness of these phenomena will depend on the particular bearing application.

1.7.2 The method of static safety factor calculation

When determining the bearing size according to static load rating (*† chapter 1.8*), one must consider a certain relationship, known as the static safety factor s_0 , between the static load rating C_0 and the maximum static load P_0 . The static safety factor s_0 determines the degree of safety against excessive permanent deformation of the rolling elements and raceways. The static load rating, C_0 , is defined as the static load that would produce a permanent deformation of 0,0001 times the rolling element diameter. Experience shows that, depending on the contact conditions, a maximum Hertzian pressure of 4 000 MPa is permissible at the zone of maximum load without affecting the running qualities of the bearing. See also ISO 14728-2.

Calculation of the static safety factor

For a chosen precision rail guide and a defined load case, the static safety factor s_0 can be calculated by:

$$s_0 = \frac{C_{0, \text{eff slide}}}{P_0} = \frac{C_{0, \text{eff slide}}}{F_{\text{res max}}}$$

where

s_0 = static safety factor

$C_{0, \text{eff slide}}$ = effective static load rating of a slide [N]

P_0 = maximum static load [N]

$F_{\text{res max}}$ = maximum resulting load [N]

Based on practical experience, guideline values have been specified for the static safety factor s_0 , which depend on the operating mode and other external factors (*† table 4*). If, for example, the precision rail guide system is exposed to external vibrations from machinery in close proximity, higher safety factors should be applied. Moreover, the load transfer paths between a precision rail guide system and its support structure should be taken into account. In particular, the screw connections must be examined for adequate safety. For overhead installations of precision rail guides, higher safety factors should be applied.

Note: The general technical rules and standards in the respective industrial sector also must be observed.

Table 4

Static safety factor depending on operating conditions

Operating conditions	s_0
Normal conditions	> 1–2
Smooth, vibration-free operation	> 2–4
Medium vibrations or impact loads	3–5
High vibrations or impact loads	> 5
Overhead installations	The general technical rules and standards in the respective industrial sector must be observed. If the application poses a risk of serious injury, the user must take appropriate design and safety measures that will prevent all rails from becoming detached from the base (e.g. due to loss of rolling elements or failure of screw connections).

Requisite static load rating

For specific operating conditions with a related recommended static safety factor and a defined load case, the requisite static load rating C_0 can be calculated from the following formula:

$$C_{0, \text{eff slide}} = s_0 P_0 = s_0 F_{\text{res max}}$$

where

$C_{0, \text{eff slide}}$ = effective static load rating of a slide [N]
 P_0 = maximum static load [N]
 s_0 = static safety factor
 $F_{\text{res max}}$ = maximum resulting load [N]

1.7.3 Rating life

In laboratory tests and in practice it is found that the rating life of apparently similar bearings under completely identical running conditions can differ. Therefore, calculation of the appropriate bearing size requires a full understanding of the concept of bearing rating life. All references to the dynamic load rating of SKF precision rail guides apply to the basic rating life, as covered by the ISO definition (ISO 14728-1), in which the rating life is understood as the life reached or exceeded by 90% of a large group of identical bearings. The majority of the bearings reach a longer rating life, and half the total number of bearings reach at least five times the basic rating life.

1.7.4 Rating life calculation

The rating life of precision rail guides expressed in km, L_{ns} , can be calculated using the following formula:

$$L_{ns} = c_1 \frac{100}{P} \frac{|C_{\text{eff slide}}|^p}{J}$$

In load cases where the length of travel and stroke frequency is constant, it is often more useful to calculate the rating lives in operating hours L_{nh} using formula 4:

$$L_{nh} = c_1 \frac{5 \cdot 10^7}{S n 60} \frac{|C_{\text{eff slide}}|^p}{P} J$$

where

L_{ns} = modified basic rating life [km]
 L_{nh} = modified basic rating life [h]
 c_1 = factor for reliability

$C_{\text{eff slide}}$	= effective dynamic load rating of a slide [N]
P	= equivalent dynamic load [N]
p	= life exponent; $p = 3$ for balls, $p = 10/3$ for rollers
n	= stroke frequency [double strokes/min]
S	= single stroke length [mm]

Note: The concept of rating life calculation is only valid in cases where the equivalent dynamic load P does not exceed 50% of the dynamic load rating C . See also the indication for static calculation in chapter 1.7.1.

Note: The life of a precision rail guide can be calculated to a degree of precision and reliability governed by the accuracy of the information about the load case and the known or calculable operating conditions.

Note: Lifetime calculation is related to the physical effect of fatigue of material. Fatigue is the result of shear stresses cyclically appearing immediately below the load carrying surface. After a time, these stresses cause cracks that gradually extend up to the surface. As the rolling elements pass over the crack, fragments of material break away. This process is known as flaking or spalling. The flaking progressively increases and eventually makes the bearing unserviceable.

Factor c_1 for reliability

Factor c_1 is used in the calculation of bearing life in cases where the intended prediction of reliability has to exceed 90%. The corresponding values for c_1 are given in table 5.

1.7.5 Service life

In addition to rating life, there also exists the concept of "service life". This term describes the period of time for which a given linear bearing remains operational in a given set of operating conditions. Therefore, the service life of the bearing depends not necessarily on fatigue but also on wear, corrosion, failure of seals, lubrication intervals (grease life), misalignment between the rails, vibration during standstill, etc. Normally, the service life only can be quantified in tests under realistic operating conditions or by comparison with similar applications.

1.7.6 Cross reference to related chapters

For the two dimensioning concepts presented in this chapter, static safety factor and basic rating life, the following input data is needed:

- The loads acting on the precision rail guide system. Their calculation will be explained in detail in chapter 1.9.
- The effective static and dynamic load rating of a certain precision rail guide system. Their calculation will be presented in the next chapter.

Table 5

Factor c_1 for reliability		
Reliability %	L_{ns}	c_1
90	L_{10s}	1
95	L_{5s}	0,62
96	L_{4s}	0,53
97	L_{3s}	0,44
98	L_{2s}	0,33
99	L_{1s}	0,21

Fig. 7

1.8 Determination of effective load ratings

For a slide equipped with four precision rails and two rolling element assemblies with an individual number of rolling elements († fig. 11), the effective static and dynamic load rating are calculated by:

$$C_{0,\text{eff slide}} = f_{h0} f_t C_{0,10} \frac{z_T 2}{10 f_1}$$

$$C_{\text{eff slide}} = f_h f_t C_{10} \left(\frac{z_T 2}{10 f_1} \right)^w$$

where

$C_{0,\text{eff slide}}$ = effective static load rating of a slide [N]

$C_{0,10}$ = basic static load rating of a rail guide with specified number of rolling elements [N]

f_{h0} = factor for hardness, static

f_t = factor for operating temperature

z_T = number of load carrying rolling elements (per cage or per row for needle rollers)

f_1 = factor for load direction

$C_{\text{eff slide}}$ = effective dynamic load rating of a slide [N]

C_{10} = basic dynamic load rating of a rail guide with specified number of rolling elements [N]

f_h = factor for hardness, dynamic

w = rolling element exponent;
 $w = 0,7$ for balls,
 $w = 7/9$ for rollers

1.8.1 Static and dynamic load ratings given in the catalogue

The basic load ratings C_{10} and $C_{0,10}$ quoted in the product data tables of rolling element assemblies are defined for one rail guide loaded in the direction shown in fig. 7 and the following amount of rolling elements:

- For 10 balls under load († fig. 8)
- For 10 crossed rollers under load († fig. 9)
- For 20 needle rollers under load (2×10 needle rollers per row) († fig. 10)

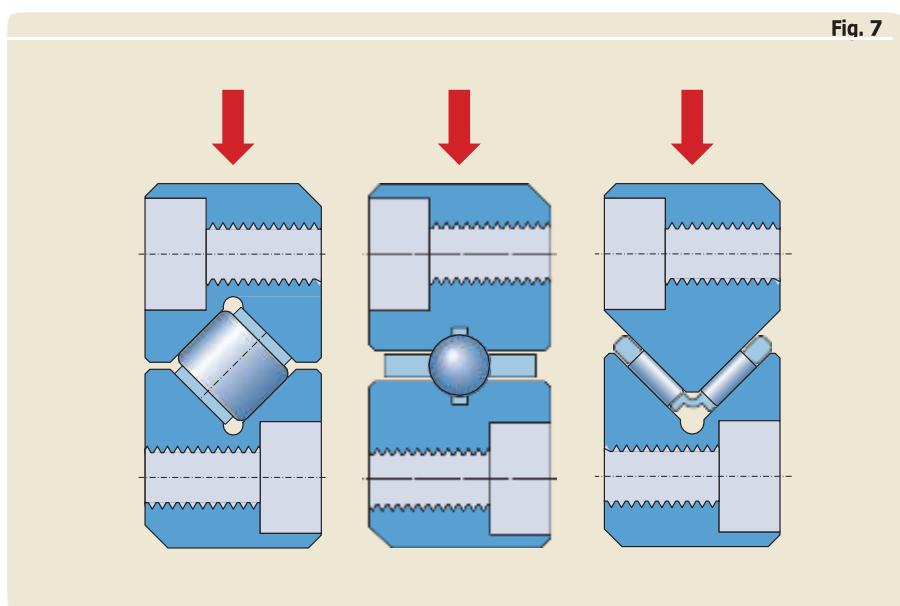

Fig. 8

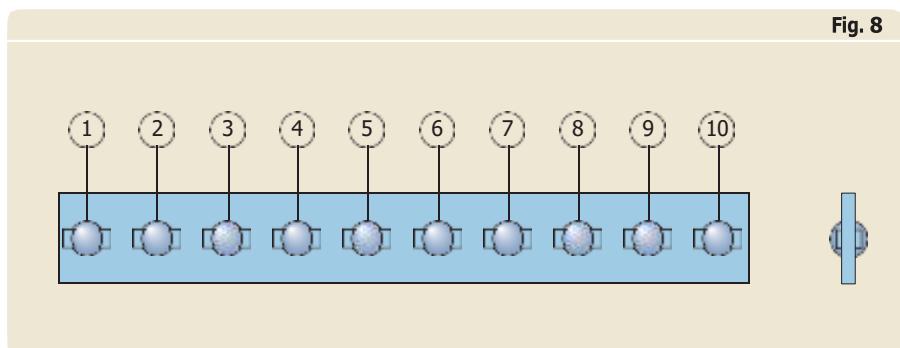

Fig. 9

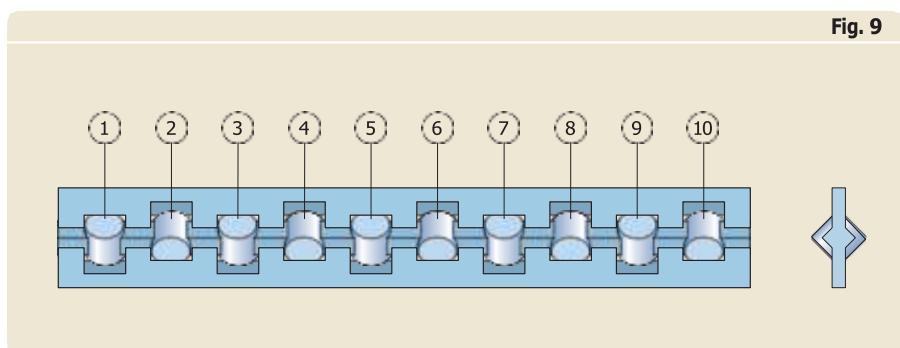

Fig. 10

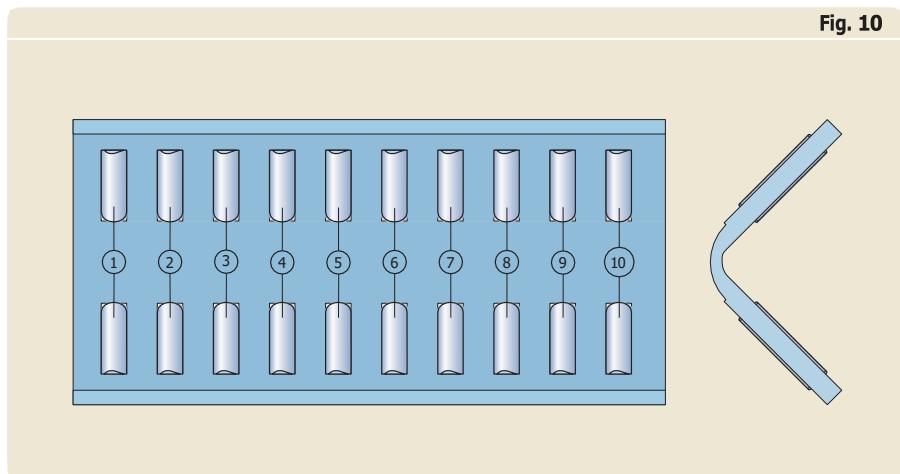

Diagram 4

Factor f_h for the influence of hardness

The full load rating of the rolling element assembly can be utilized completely (both factors equal 1) only if the surface hardness of the raceways is at least 58 HRC. If rails of stainless or acid-resistant steel are used and their raceway hardness doesn't reach the required limit, the values for the factors f_h and f_{h0} can be obtained from **diagram 4**. If rolling elements with a lower hardness, e.g. made from stainless steel, are used, the same factor has to be considered.

Note: The static and dynamic load ratings for rolling element assemblies with ACSM, given in the product tables, already are reduced. The corresponding rails are made from stainless steel by standard. For this speciality, it is not useful to additionally utilize the factors $f_{h0} < 1$ and $f_h < 1$.

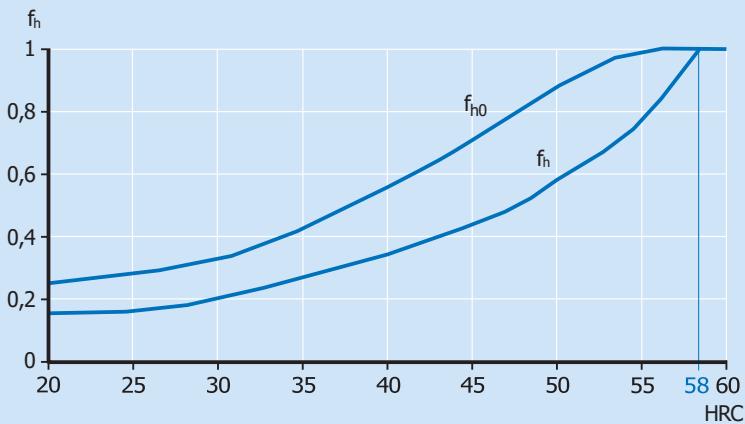

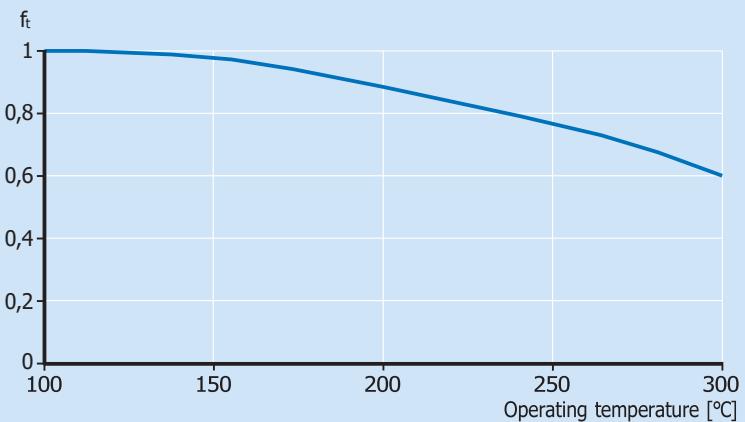

Diagram 5

Factor f_t for the influence of operating temperature

1.8.3 Influence of operating temperature

When a precision rail guide without plastic cage is permanently used with operating temperatures above +120 °C, the load ratings will decrease by a certain amount. In such cases, the temperature factor f_t has to be taken into consideration. Values of factor f_t can be obtained from **diagram 5** as a function of the operating temperature.

1.8.4 Rail guide arrangements

Precision rail guides can be mounted in several types of arrangements, to suit the requirements of the particular application. Two of these are described below. The impact of the two types of arrangements on the load ratings is expressed in factor f_1 for load direction († **fig. 11**).

Clamped arrangement

The most common way to design a precision rail guide system is the clamped arrangement, as it has several advantages:

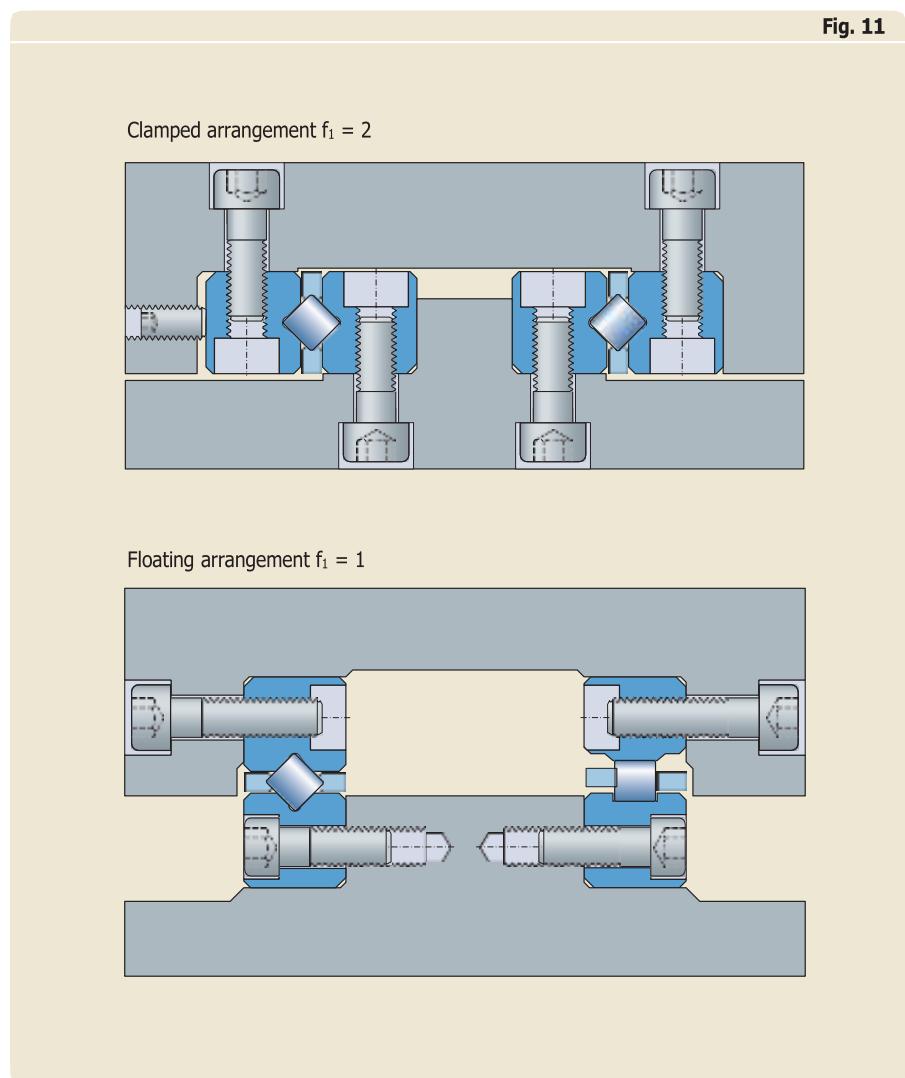

- The rails can be preloaded to meet demands for rigidity and running accuracy.
- The system can accommodate loads and moments in any direction.
- It has a small cross section for compact construction.

As a rule, rail guide systems in clamped arrangements consist of two identical precision rail guides, as shown in **fig. 11**. With rail guides in such an arrangement, it is even possible to adjust the preload, such as by using set screws, as explained in chapter 3.1.10.

Floating arrangement

A rail guide system in a floating arrangement consists of a "locating" bearing e.g. a LWR rail guide, which provides guidance in the longitudinal and lateral directions, and another rail guide with two flat raceways, which acts as the "non-locating" bearing († **fig. 11**). In such arrangements, care should be taken to ensure that both guide systems are of similar load rating and rigidity. Rail guide systems in floating arrangement are able to take up loads that are predominantly vertical only. However, they can support heavy loads and are simple to mount. They can be used to advantage where:

- Thermal expansion must be compensated
- Large distances between supports have to be bridged

1.8.5 Rail guide kinematics

Depending on the application, considering the available space, stroke and environmental conditions, precision rail guide systems can be designed in different ways. Possible kinematics and their individual characteristics are described in the next chapters. When selecting the dimension of a rail guide and rolling element assembly, the requirements regarding geometry and installation space or the requirements regarding load rating and rigidity are of primary importance. In the first case, the maximum applicable cage length is calculated depending on stroke and length of the rails. The given equations are transformed, if load capacity or rigidity requirements determine the length of the cage. In this case, the length of the rails is calculated depending on the length of the cage and stroke.

Fig. 12

Not overrunning systems without wipers

The rolling element assembly always moves half the distance travelled by the moving rail and remains between the rails († fig. 12).

In case the geometry is given

$$L_{cage, max} = L_{rail} - 0,5 S$$

or the rating life / rigidity defined the length of the rolling element assembly

$$L_{rail, min} = L_{cage} + 0,5 S$$

where

$L_{cage, max}$ = maximum length of rolling element assembly, if rail length and stroke are predefined [mm]

L_{rail} = length of the rail [mm]

$L_{rail, min}$ = minimum length of the rail, if length of cage and stroke are predefined [mm]

L_{cage} = length of rolling element assembly [mm]

S = intended stroke length [mm]

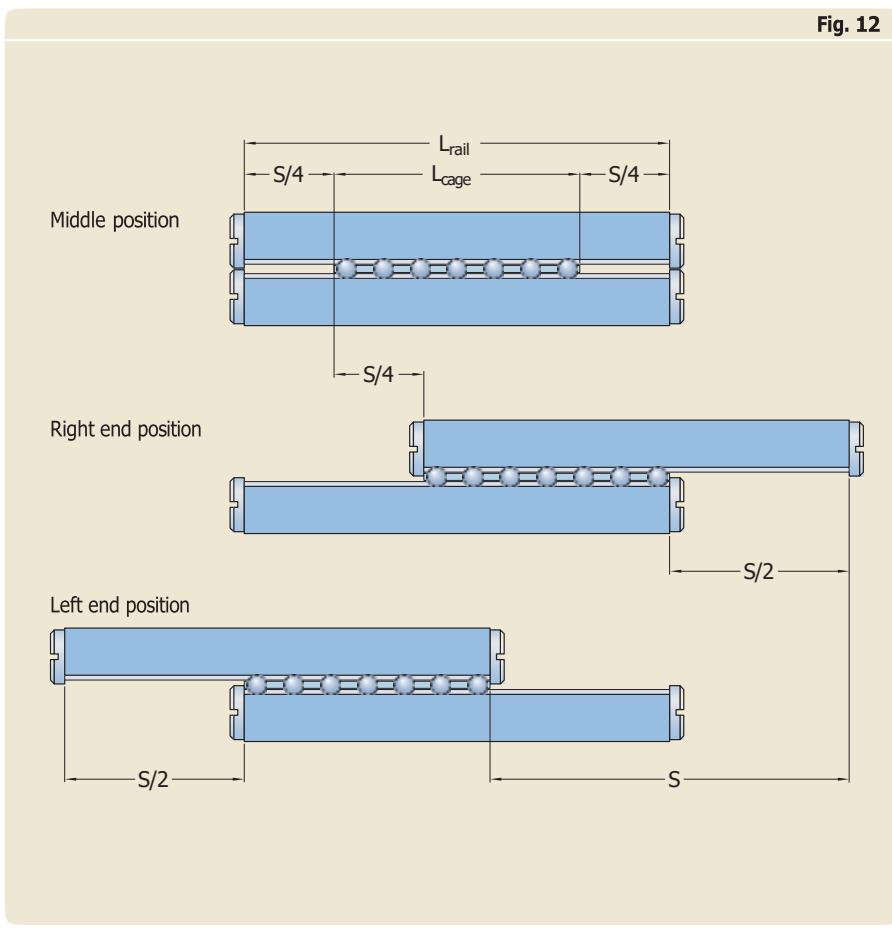

Fig. 13

Precision rail guide system with wipers

If the rail guide has to be sealed with wipers, it is important to ensure that the lips of the wipers seal against the raceway of the opposing rail over the whole length of travel. Normally, the rail guide arrangement is fitted with two rails of different length. The wipers are attached to the shorter rail, of which the length is determined according to the formulas given above under heading *Not overrunning systems without wipers*. The minimum length of the long rail is († fig. 13)

$$L_{rail, long, min} = L_{cage} + 1,5 S + 2 L_1$$

or in case the geometry is given

$$L_{cage, max} = L_{rail, long} - 1,5 S - 2 L_1$$

where

$L_{rail, long, min}$ = minimum length of the long rail, if length of cage and stroke are predefined [mm]

L_{cage} = length of rolling element assembly [mm]

L_1 = thickness of end piece with wiper [mm]

$L_{cage, max}$ = maximum length of rolling element assembly, if rail length and stroke are predefined [mm]

$L_{rail, long}$ = length of the long rail [mm]

S = intended stroke length [mm]

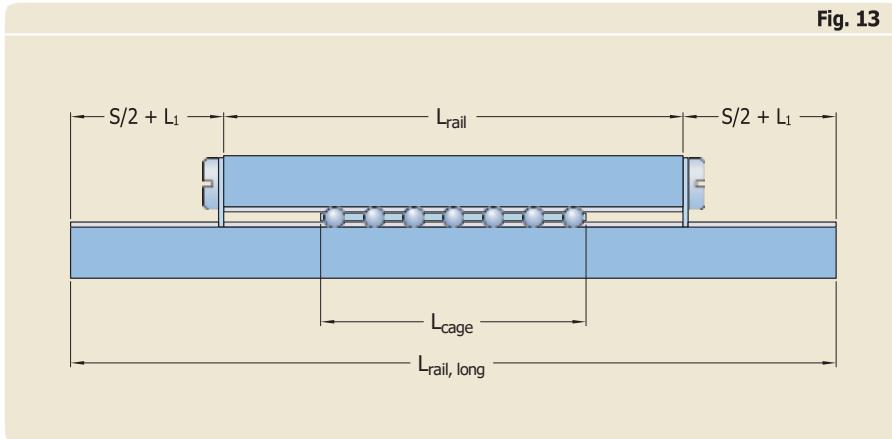

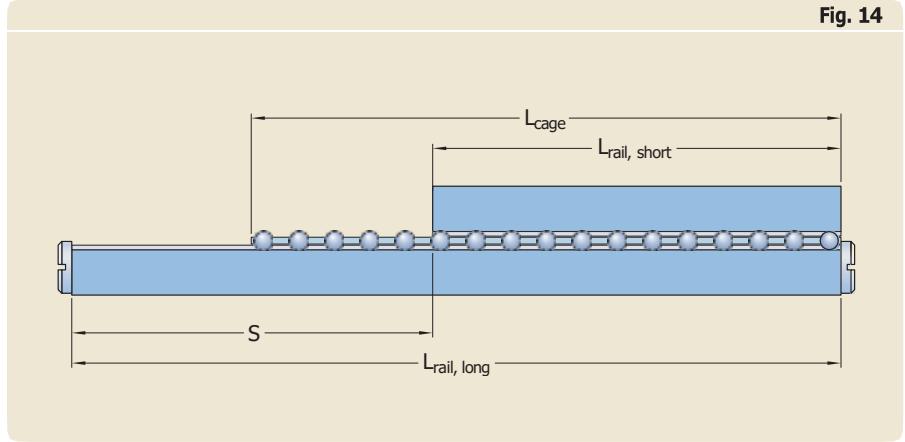

Fig. 14

Overrunning system without wipers

If a short precision rail moves on a long rail, overrunning rolling element assemblies should be preferred. It is important that the short rail has lead in radius at both rail ends (ordered with suffix "EG") so that the overrunning cage causes as little pulsation as possible. Not every cage is suitable for this application. The maximum cage overrun ("free length" of the cage) depends on the orientation of the rails and on the cage material.

In case of priority of installation space, the length of the components is calculated by († fig. 14)

$$L_{\text{cage, max}} = L_{\text{rail, long}} - 0,5 S$$

and

$$L_{\text{rail, short}} = L_{\text{rail, long}} - S$$

If rigidity or load rating are more important

$$L_{\text{rail, long}} = L_{\text{cage}} + 0,5 S$$

and

$$L_{\text{rail, short}} = L_{\text{rail, long}} - S$$

where

$L_{\text{cage, max}}$ = maximum length of rolling element assembly, if rail length and stroke are predefined [mm]

$L_{\text{rail, long}}$ = length of the long rail [mm]

$L_{\text{rail, short}}$ = length of the short rail in an overrunning system [mm]

L_{cage} = length of rolling element assembly [mm]

S = intended stroke length [mm]

1.8.6 Number of rolling elements z , z_T

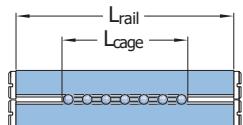

After the calculation of the maximum cage length $L_{cage, max}$ and the length of the rails according to demanded geometry, the number of rolling elements z has to be calculated for ordering the right length of rolling element assembly. Depending on the different

kinematic types the number of load carrying elements z_T has to be defined for the calculation of the rating life. The following overview shows the formulas for z and z_T . For kinematic types, where the rolling element assembly always remains between the rails (not overrunning rail guide without wipers and rail guide with wipers) and all rolling elements carry load, $z = z_T$ is valid. In

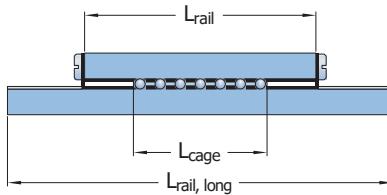

overrunning systems, only the rolling elements underneath the short rail can carry load, and z_T has to be calculated differently.

The formulas are using the function "truncate" to get an integer number of rolling elements. With that, the real cage length for ordering L_{cage} and the load carrying length L_T , defined from the center of the first load carrying rolling element to the center of

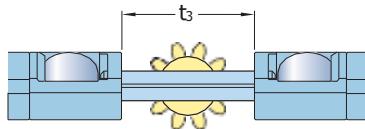

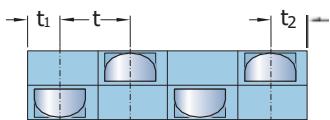

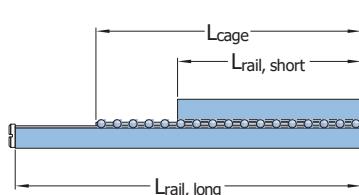

Not overrunning rail guide without wipers (Standard)

Rail guide with wipers

Overrunning rail guide without wipers

Values for t , t_1 , t_2 and t_3 for the different cage types are given in the chapter *Product data 2.1–2.7*.
if no value for t_2 is given: $t_2 = t_1$
if no value for t_3 is given: $t_3 = 0$

$$z = \text{TRUNC} \left\lfloor \frac{L_{cage, max} - t_1 - t_2 - t_3}{t} \right\rfloor + 1$$

$$z_T = \text{TRUNC} \left\lfloor \frac{L_{cage, max} - t_1 - t_2 - t_3}{t} \right\rfloor + 1$$

$$z_T = \text{TRUNC} \left\lfloor \frac{L_{rail, short} - t_3 - 2 \cdot EG}{t} \right\rfloor + 1$$

$$L_{cage} = (z - 1) t + t_1 + t_2 + t_3$$

$$L_T = (z_T - 1) t + t_3$$

$$L_{install} = L_{rail} + S + 2 L$$

$$L_{install} = L_{rail, long}$$

$$L_{install} = L_{rail, long} + 2 L$$

Legend:

- z = number of rolling elements (per cage or per row for needles)
- z_T = number of load carrying rolling elements (per cage or per row for needles)
- L_{cage} = length of rolling element assembly [mm]
- $L_{cage, max}$ = maximum length of rolling element assembly [mm]
- L_T = load carrying length [mm]
- $L_{rail, short}$ = length of the shorter rail in an overrunning system [mm]
- $L_{rail, long}$ = length of the long rail [mm]
- t = pitch of rolling elements in a cage [mm]
- t_1, t_2 = distance of outer rolling element to the end of cage [mm]
- t_3 = length of anti-creeping system [mm]
- EG = length of lead in radius on each side, typically 1–2 mm [mm]
- $L_{install}$ = length of the complete installation space [mm]
- L = thickness of the end piece [mm]

Note: "TRUNC" is the mathematical function that truncates a number to an integer by removing the fractional part of the number.

Fig. 15

the last, can be calculated. Additionally the formulas for the installation length L_{install} are given.

1.8.7 General geometry of a rail guide system

As a general recommendation, the length of a rolling element assembly can be chosen using the following guidelines:

"clamped" arrangement $L_{\text{cage}} = S$

"floating" arrangement $L_{\text{cage}} = 1,5 S$

where

L_{cage} = length of rolling element assembly [mm]

S = intended stroke length [mm]

It should be remembered, however, that where loads are heavy, applied off-centre, or include torque loads, the longest possible rolling element assembly should be chosen to achieve both, an even load distribution and high rigidity.

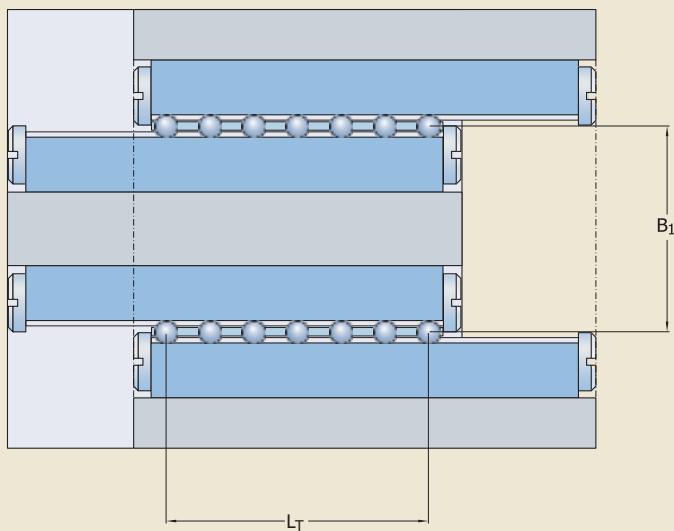

A further recommendation is that the mean distance between the rolling element assemblies B_1 should not exceed the load-carrying length L_T († **fig. 15**):

$$L_T > B_1$$

where

B_1 = mean distance between the rolling element assemblies [mm]

L_T = load carrying length [mm]

1.9 Calculation of bearing loads

The load can be directly inserted into the rating life equations and the static safety factor equation, if the load F acting on a rail guide is constant in magnitude, position and direction and acts vertically and through the centre of the raceway. In all other cases, it is first necessary to calculate the maximum resulting load $F_{\text{res}, \text{max}}$ and the equivalent dynamic load P . These representative loads are defined as the loads that would have the same influence on the rating life and on the static safety factor s_0 as the real set of loads.

How to deal with loads that are not vertically and not through the center of the rail guide system is described in chapter 1.9.1, and 1.9.3. How to deal with time- or position-varying loads will be explained in chapter 1.9.5.

1.9.1 Transfer of external loads to F_y , F_z , M_x , M_y , M_z

First, the coordinate system for the selected layout has to be defined. It is preferred to define the moving direction as x -axis. The origin of the coordinate system is set to the middle of the rolling element assembly and all lever arms in x -direction are measured from there. This means, that the coordinate system moves and that lever arms change

with the movement of the guiding († fig. 16). In the other directions, the origin should be symmetrically between the rolling element assemblies at $B_1/2$ and on the rails center height († chapter 1.6.11).

Second, all working loads, that have impact on the rail guide system, have to be collected. Load directions and lever arms must not be ignored. The single external loads are summarized to a set of five values: F_y , F_z , M_x , M_y , M_z . These five values are calculated by

$$F_y = \sum_{i=1}^U F_{y,i}$$

$$F_z = \sum_{i=1}^U F_{z,i}$$

$$M_x = - \sum_{i=1}^U F_{y,i} z_i + \sum_{i=1}^U F_{z,i} y_i$$

$$M_y = \sum_{i=1}^U F_{x,i} z_i - \sum_{i=1}^U F_{z,i} x_i$$

$$M_z = - \sum_{i=1}^U F_{x,i} y_i + \sum_{i=1}^U F_{y,i} x_i$$

where

$F_{x,i}$, $F_{y,i}$, $F_{z,i}$ = single loads in x -, y - or z -direction that act simultaneously on the rail guide system [N]

F_y , F_z = summarized force (load) in y - or z -direction [N]

M_x , M_y , M_z = summarized torque load in x -, y - or z -direction [Nm]

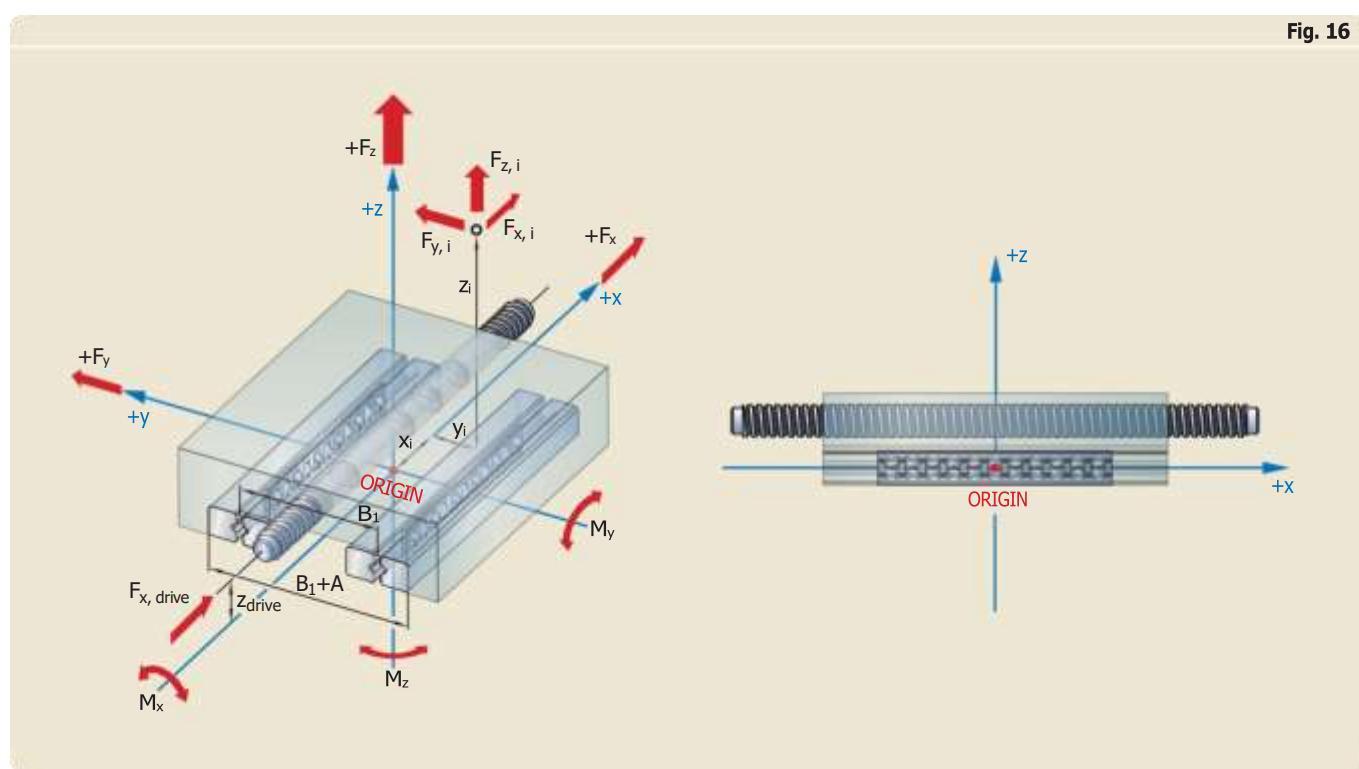

x_i , y_i , z_i = lever arms that are related to the single loads [m]

i = counter for single loads in x -, y - or z -direction that act simultaneously

U = amount of loads that act simultaneously

Note: The given set of five values, F_y , F_z , M_x , M_y , M_z , are independent of the concrete geometry of the rail guide system.

The premise for the next calculation steps is that the type and length of rolling element assembly is chosen and the related characteristic values C , C_0 and L_T are defined. Additionally, a value for the mean distance between rolling element assemblies, B_1 , needs to be defined († chapter 1.8.7).

1.9.2 Preload force

The additional load generated by the preload in a clamped arrangement has to be considered during the dimensioning calculation. The factor for preload, f_{Pr} , depends on the type of rolling element assembly. († chapter 3.1.9). This so-called preload force is calculated by

$$F_{Pr} = C_{eff} f_{Pr}$$

$$C_{eff} = C_{eff\ slide} \text{ for clamped arrangement}$$

Where

F_{Pr} = preload force [N]

C_{eff} = effective dynamic load capacity for one rolling element assembly [N]

f_{Pr} = factor for preload, %

1.9.3 Transfer of F_y , F_z , M_x , M_y , M_z to one load

The set of five load values F_y , F_z , M_x , M_y , M_z are summed up to the combined bearing load

$$F_{comb} = |F_y| + |F_z| + \left| \frac{|2000 M_x|}{B_1} + \frac{|6000 M_y|}{L_T} + \frac{|6000 M_z|}{L_T} \right|$$

The resulting load F_{res} , that includes the preload force F_{Pr} , is used for the static dimensioning.

$$F_{res} = F_{Pr} + F_{comb} = F_{Pr} + |F_y| + |F_z| + \left| \frac{|2000 M_x|}{B_1} + \frac{|6000 M_y|}{L_T} + \frac{|6000 M_z|}{L_T} \right|$$

The equivalent dynamic load P , that considers the factor for stroke length f_s , is used for dynamic dimensioning.

$$P = f_s F_{res} = f_s (F_{Pr} + |F_y| + |F_z| + \left| \frac{|2000 M_x|}{B_1} + \frac{|6000 M_y|}{L_T} + \frac{|6000 M_z|}{L_T} \right|)$$

where

F_{comb} = combined bearing load

F_{res} = resulting load [N]

F_{Pr} = preload force [N]

F_y , F_z , = summarized force (load) in y- or z-direction [N]

M_x , M_y , M_z = summarized torque load in x-, y- or z-direction [Nm]

B_1 = mean distance between the rolling element assemblies [mm]

L_T = load carrying length [mm]

P = equivalent dynamic load [N]

f_s = factor for stroke length

1.9.4 Influence of stroke length on equivalent dynamic load rating

When defining the operating conditions for the calculation of the basic rating life, it is assumed that the reference stroke length for the precision rail guide is equal to the length of the rolling element assembly. In precision rail guide applications, however, this rarely applies. Exhaustive life tests have shown that there is a reduction in the life of a precision rail operated with a short stroke length. This influence of the stroke length in relation to the length of the rolling element assembly is shown in **diagram 6**. For ratios greater than 0,6, the reduction in rating life is insignificant, but for lower values, the factor f_s modifies the equivalent dynamic load. In the case of values under 0,1, unfavourable tribological conditions render the calculation of bearing life impractical. Under such conditions, the rating life is determined largely by the sliding conditions in the contact zone.

1.9.5 Equivalent dynamic mean load

The rating life calculation formulas are based on the assumption that the load and the speed are constant. In reality the external loads, positions and speeds are changing in most cases and the workflow has to be separated into load phases with constant or approximately constant conditions along their individual strokes. Since the lever arms in x-direction are changing with the movement of the guiding, the equivalent dynamic load is varying continuously and for calculations without electronical devices simplifications have to be made (**† diagram 7**). All single load phases are summarized to the equivalent dynamic mean load P_m depending on their individual stroke length:

$$P_m = \sqrt[1/p]{\sum_{j=1}^V |P_j|^p / S_j}$$

$$S_{tot} = S_1 + S_2 + S_3 \dots + S_v$$

Diagram 6

Factor f_s for the influence of stroke length

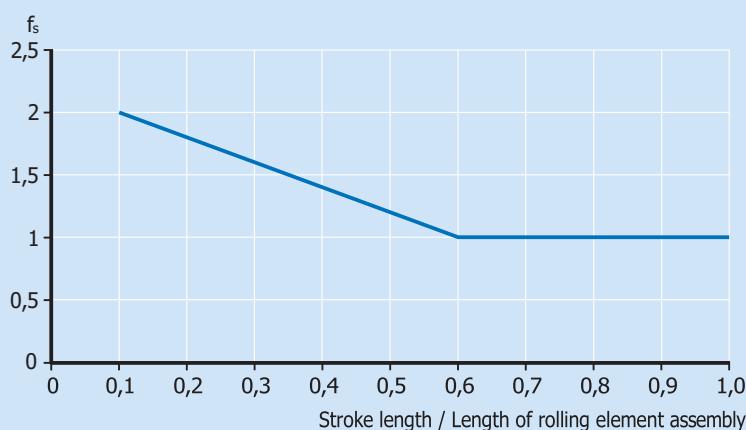

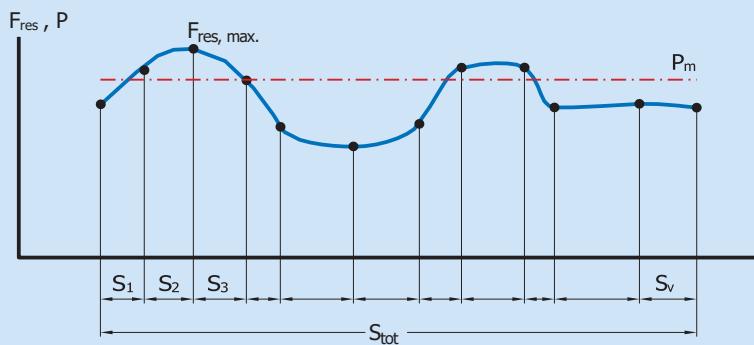

Diagram 7

Variable load on a precision rail guide

where

P_m = equivalent dynamic mean load [N]

P = equivalent dynamic load [N]

p = life exponent;

$p = 3$ for balls,

$p = 10/3$ for rollers

j = counter for load phases

V = amount of load phases

S_j = individual stroke length [mm]

S_{tot} = total stroke length [mm]

1.9.6 Maximum resulting load

The maximum value of F_{res} is required for calculating the static safety factor s_0 . To this end, all loads must be calculated for the individual stroke lengths. With these figures, the maximum resulting load $F_{res, max}$ can be calculated and then inserted in the equation for s_0 .

Note: The distance to the reversal points is relevant for the determination of the factor f_s . Sequenced load phases with identical moving direction deliver one complete stroke length.

$$F_{res, max} = \max_{j=1}^v |F_{res,j}|$$

$$F_{res, max} = \max (F_{Pr} + |F_y| + |F_z| + \left| \frac{2000 M_x}{B_1} \right| + \left| \frac{6000 M_y}{L_T} \right| + \left| \frac{6000 M_z}{L_T} \right|^r)$$

1.9.7 Elaborated equation for the static safety factor

All given equations related to the static safety factor can be integrated into one formula:

$$S_0 = \frac{C_{0, eff, sli - d - e -}}{F_{res, max}} = \frac{f_h f_t C_{10} \frac{z_T^2}{10 f_1 f}}{\max_{j=1}^v \left(F_{Pr} + |F_y| + |F_z| + \left| \frac{2000 M_x}{B_1} \right| + \left| \frac{6000 M_y}{L_T} \right| + \left| \frac{6000 M_z}{L_T} \right|^r \right)}$$

1.9.8 Elaborated equation for the rating life

All given equations related to the rating life calculation can be integrated into one formula:

$$L_{ns} = c_1 100 \left| \frac{C_{eff, sli, de}}{P_j} \right| = c_1 100 \left| \frac{f_h f_t C_{10} \frac{z_T^2}{10 f_1 f} r^p}{\sum_{j=1}^p S_j} \right|$$

$$L_{ns} = c_1 100 \left| \frac{f_h f_t C_{10} \frac{z_T^2}{10 f_1 f} r^p}{\sum_{j=1}^p \left(\frac{|F_{Pr}| + |F_{y,j}| + |F_{z,j}|}{B_1} + \left| \frac{2000 M_{x,j}}{L_T} \right| + \left| \frac{6000 M_{y,j}}{L_T} \right| + \left| \frac{6000 M_{z,j}}{L_T} \right|^r \right) S_j} \right|$$

$$L_{ns} = c_1 100 \left| \frac{f_h f_t C_{10} \frac{z_T^2}{10 f_1 f} r^p}{\sum_{j=1}^p \left(\frac{|F_{Pr}| + |F_{y,j}| + |F_{z,j}|}{B_1} + \left| \frac{2000 M_{x,j}}{L_T} \right| + \left| \frac{6000 M_{y,j}}{L_T} \right| + \left| \frac{6000 M_{z,j}}{L_T} \right|^r \right) S_j} \right|$$

1.10 Example dimensioning calculation

The customised SKF precision rail guide slide we will use for this example is equipped with an ironless linear motor with high velocity constancy as drive, with a sealed optical encoder and with mechanical end stops. The shown design is typical for precision rail guide slides († **fig. 17**).

Description of the application

A construction part (mass 40 kg, length 150 mm, width 100 mm, height 90 mm) has to be moved in several process steps to perform a measurement. The first step is a very precise movement over its entire length. The measurement can be performed at a maximum acceleration of 1 m/s² and is running at constant room temperature of 22 °C. The next process step, which is done at standstill, creates a load of 600 N downward in z-direction located symmetrically between the precision rail guide units and in x-direction 20 mm inside the construction part. The available construction space limits L_{rail} by 250 mm. To have a certain reserve, the intended stroke of the slide is 160 mm. For forward and backward stroke the values for acceleration and deceleration are equal. Because of the high demands on repeatability of running accuracy in height- and sideward direction, an anti-creeping system is required. So the precision rail guides with ACSM have to be used.

Questions to be answered:

- Which precision rail guide (size, L_{cage}) is sufficient for this application?
- Which maximum stroke will be possible?
- Which static safety factor and rating life in kilometers can be achieved?

Maximum length of rolling element assembly

In this example the geometry is given by the construction space and the demanded stroke. According to *chapter 1.8.5*, following formula has to be used:

$$L_{cage, max} = L_{rail} - 0,5 S$$

$$\begin{aligned} L_{cage, max} &= 250 \text{ mm} - 0,5 \cdot 160 \text{ mm} \\ &= 170 \text{ mm} \end{aligned}$$

Number of rolling elements z, z_T

Because of the chosen kinematic – not overrunning cage without wipers, all rolling elements carry load all the time and z = z_T. To calculate a real value of z, a certain type and size of rolling element assembly has to be chosen. Because of the fact that mass and external load are not too heavy in this example we start the calculation with the smallest possible cage type LWJK 2 ACSM which may fulfill the requirements. When checking the maximum rail length of LWRB2 we find out that 200 mm don't cover the needs and LWRE 3 ACSM is the smallest guiding possible. Following formula has to be used, as described in *chapter 1.8.6*. The needed values are given in the relevant product chapter.

$$z = z_T = \text{TRUNC} \left\langle \frac{|L_{cage, max} - t_1 - t_2 - t_3|}{t} \right\rangle + 1$$

$$z = z_T = \text{TRUNC} \left\langle \frac{170 \text{ mm} - 2,65 \text{ mm} - 3,6 \text{ mm} - 9 \text{ mm}}{6,25 \text{ mm}} \right\rangle + 1 = 25$$

The number of rolling elements is used to calculate L_{cage} needed for ordering:

$$L_{cage} = (z - 1) t + t_1 + t_2 + t_3$$

$$L_{cage} = (25 - 1) \cdot 6,25 \text{ mm} + 2,65 \text{ mm}$$

$$+ 3,6 \text{ mm} + 9 \text{ mm} = 165,25 \text{ mm}$$

The number of rolling elements is used to calculate the load carrying length L_T:

$$L_T = (z_T - 1) t + t_3$$

$$L_T = (25 - 1) \cdot 6,25 \text{ mm} + 9 \text{ mm} = 159 \text{ mm}$$

With the exact length of the cage, the resulting maximum stroke can be calculated.

$$S = (L_{rail} - L_{cage}) 2$$

$$S = (250 \text{ mm} - 165,25 \text{ mm}) \cdot 2 = 169,5 \text{ mm}$$

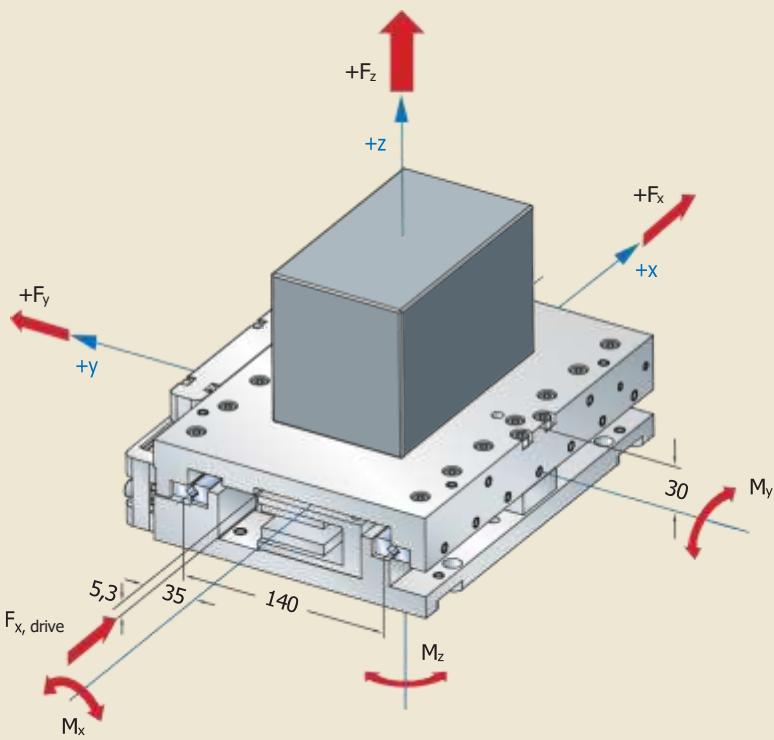

The general rules L_{cage} = S for "clamped" arrangement and L_T > B₁ are observed.

Fig. 17

RLM with coordinate system

Determination of effective load ratings

For the calculation of the static safety factor and the rating life, the effective load ratings are needed. It is important to know several determining factors as shown in **table 6**. Furthermore the values of C_{0,10} and C₁₀ of the selected rolling element assembly have to be gathered in the product chapter.

$$C_{0, \text{eff slide}} = f_{h0} f_t C_{0,10} \frac{z_T 2}{10 f_1}$$

$$C_{0, \text{eff slide}} = 1 \cdot 1 \cdot 8 \cdot 160 \text{ N} \cdot \frac{25 \cdot 2}{10 \cdot 2} = 20 \cdot 400 \text{ N}$$

$$C_{\text{eff slide}} = f_h f_t C_{10} \cdot \frac{z_T 2}{10 f_1}$$

$$C_{\text{eff slide}} = 1 \cdot 1 \cdot 5 \cdot 040 \text{ N} \cdot \frac{25 \cdot 2}{10 \cdot 2}^{\frac{7}{9}} = 10 \cdot 279 \text{ N}$$

Fig. 18

Calculation of bearing loads

Beside the effective load ratings it is also necessary to calculate the maximum resulting load $F_{res, max}$ and the equivalent dynamic mean load P_m of the application. For that, it is essential to understand the workflow of the application and where and at what time the loads are acting. In most cases it is necessary to separate the workflow into load phases with constant or nearly constant conditions.

The definition of the general coordinate system is shown in **fig. 17** at the beginning of this chapter. **Fig. 18** shows the lever arms in x-direction of load phase 6 of the example. For an explanation, where to set the coordinate system, see also *chapter 1.9.1*.

For each load phase the working loads have to be summarized to a set of five values: F_y , F_z , M_x , M_y , M_z . After that, those five values and the preload force are transferred to one load which represents the respective load phase. The workflow of the application with its single load phases and the acting loads including their lever arms of the example are shown in following systematic overview († **table Load calculation, page 34 and 35**). Also the needed formulas and calculations can be found there. Since the values for acceleration and deceleration are equal on forward and backward stroke, it is here sufficient to calculate P_m only with the load phases of the forward stroke.

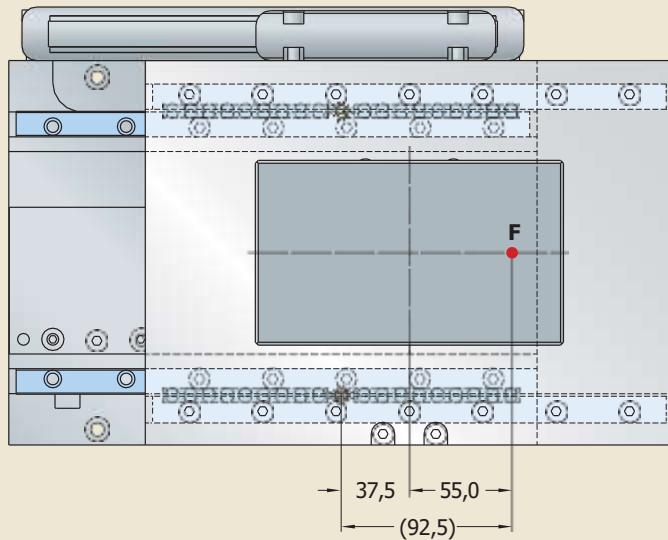

The factor for stroke length has to be determined with the help of **diagram 6**, *chapter 1.9.4*.

$$\frac{S}{L_{cage}} = \frac{150 \text{ mm}}{165,25 \text{ mm}} = 0,91 + f_s = 1$$

The preload force has to be calculated. The factor for preload f_{Pr} depends on the type of rolling element assembly († *chapter 3.1.10*).

$$F_{Pr} = f_{Pr} C_{eff\ slide}$$

$$F_{Pr} = 0,07 \cdot 10\,279 \text{ N} = 719,5 \text{ N}$$

Maximum resulting load

The maximum resulting load occurs in load phase 6.

$$F_{res, max} = \underset{j=1}{\overset{v}{\text{MAX}}} |F_{res, j}|$$

$$F_{res, max} = 4\,362 \text{ N}$$

Calculation of the static safety factor

Now for the chosen precision rail guide and the load phase with the highest resulting load, the static safety factor s_0 can be calculated.

$$s_0 = \frac{C_{0, eff slide}}{F_{res, max}}$$

$$\frac{20\,400 \text{ N}}{4\,362 \text{ N}} = 4,68$$

Equivalent dynamic mean load

For the calculation of the rating life the equivalent dynamic mean load is needed. The single values, the needed formula and the calculations are given in table *Load calculations, page 34 and 35*. The result is

$$P_m = P_5 \cdot \frac{\sum_{j=1}^v |P_j| \cdot S_j}{S_{tot}} = 1\,489 \text{ N}$$

Rating life calculation

The rating life of precision rail guides expressed in km, L_{ns} , can now be calculated using following formula:

$$\frac{|C_{eff slide}|^p}{L} = c \cdot \frac{100 \text{ km}}{P_m}$$

$$L_{10s} = 1 \cdot 100 \text{ km} \cdot \frac{10\,279 \text{ N}^{\frac{10}{3}}}{1\,489 \text{ N}} = 62\,640 \text{ km}$$

1.11 Rigidity calculation

For the user of precision rail guide systems it is of particular importance to be able to calculate the elastic deflection of the arrangement at the point where the load is applied. To get an approximation of this figure, it is at first necessary to determine the elastic deformation caused by the rolling element on the raceway d , by using one of the **diagrams 8–12**. This value has to be multiplied with factor f_k , to achieve an approximate value for the resulting deflection d_{res} , that a precision rail guide system, including the adjacent parts made of steel, will have. Following two chapters describe this procedure.

1.11.1 Determination of elastic deformation using the nomogram

When using a nomogram from **diagram 8–11** it is first necessary to establish the load conditions in relation to the mechanical dimensions and to define for which load phase and dominating single load in z-direction the elastic deformation should be calculated. **Figure 19** shows the necessary parameters required for the calculation. The rolling element diameter D_w and the contact length of rolling element $L_{w\ eff}$ can be obtained from **table 7**. After these calculations the elastic deformation for the point where the load is applied can be read off the nomogram. The nomograms are based on "clamped" rail guides (\dagger chapter 1.8.4) and relate as follows to the various types of precision rail guides.

There is a calculation example in *chapter 1.11.3*, for which **diagram 8** and **10** already contain the values and lines.

Leverage ratio 1

Preparation

Determination of number of load carrying rolling elements († chapter 1.8.5 and 1.8.6):

$$z_T = \frac{L_T}{t} + 1$$

Calculation of average rolling element load for:

Ball and crossed roller assembly:

$$\bar{Q} = \frac{z}{z_T}$$

Needle roller assembly:

$$\bar{Q} = \frac{z}{2 z_T}$$

Calculation of the leverage ratio R_x :

$$\bar{R}_x = \frac{x}{t}$$

Calculation of the leverage ratio R_y :

$$R_y = \frac{y}{B_1}$$

Where

z_T = number of load carrying rolling elements (per cage or per row for needles)

L_T = load carrying length [mm]

t = pitch of rolling elements in cage [mm]

Q = average load per rolling element [N]

F_z = single load in z-direction [N]

x = distance from centre of rolling element assembly to point of application of load [mm]

y = distance from centre of rail guide unit to point of application of load [mm]

B_1 = mean distance between the rolling element assemblies [mm]

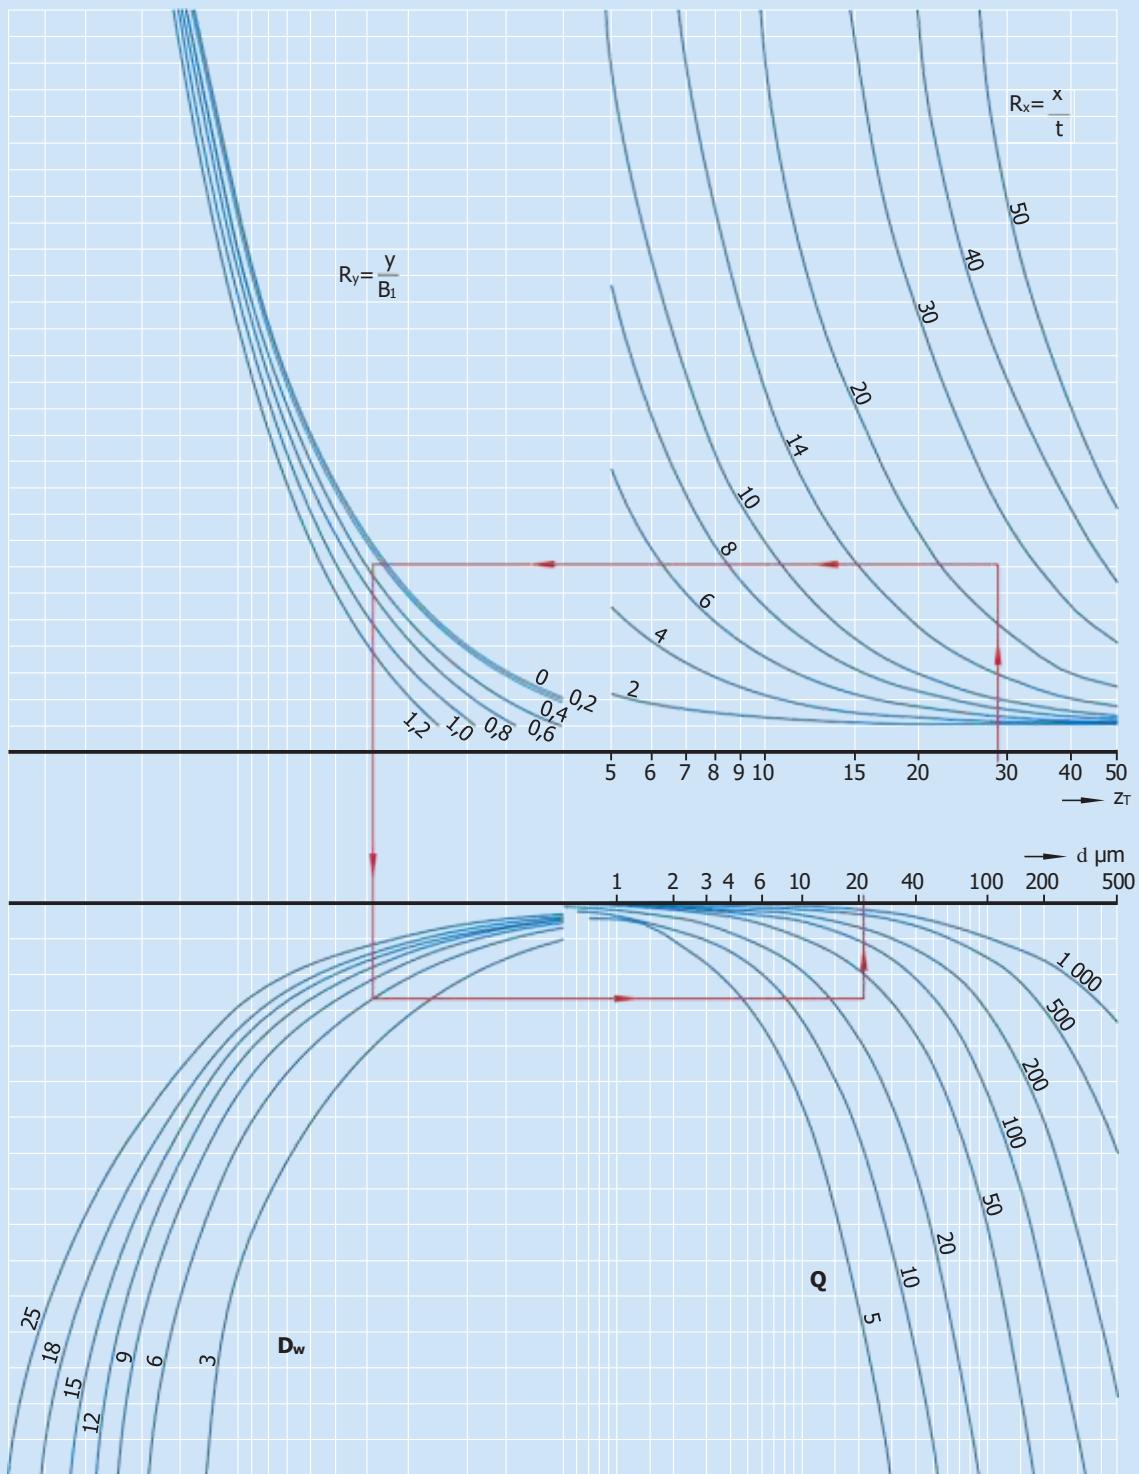

D_w = rolling element diameter [mm]

$L_{w\text{ eff}}$ = contact length of rolling element [mm]

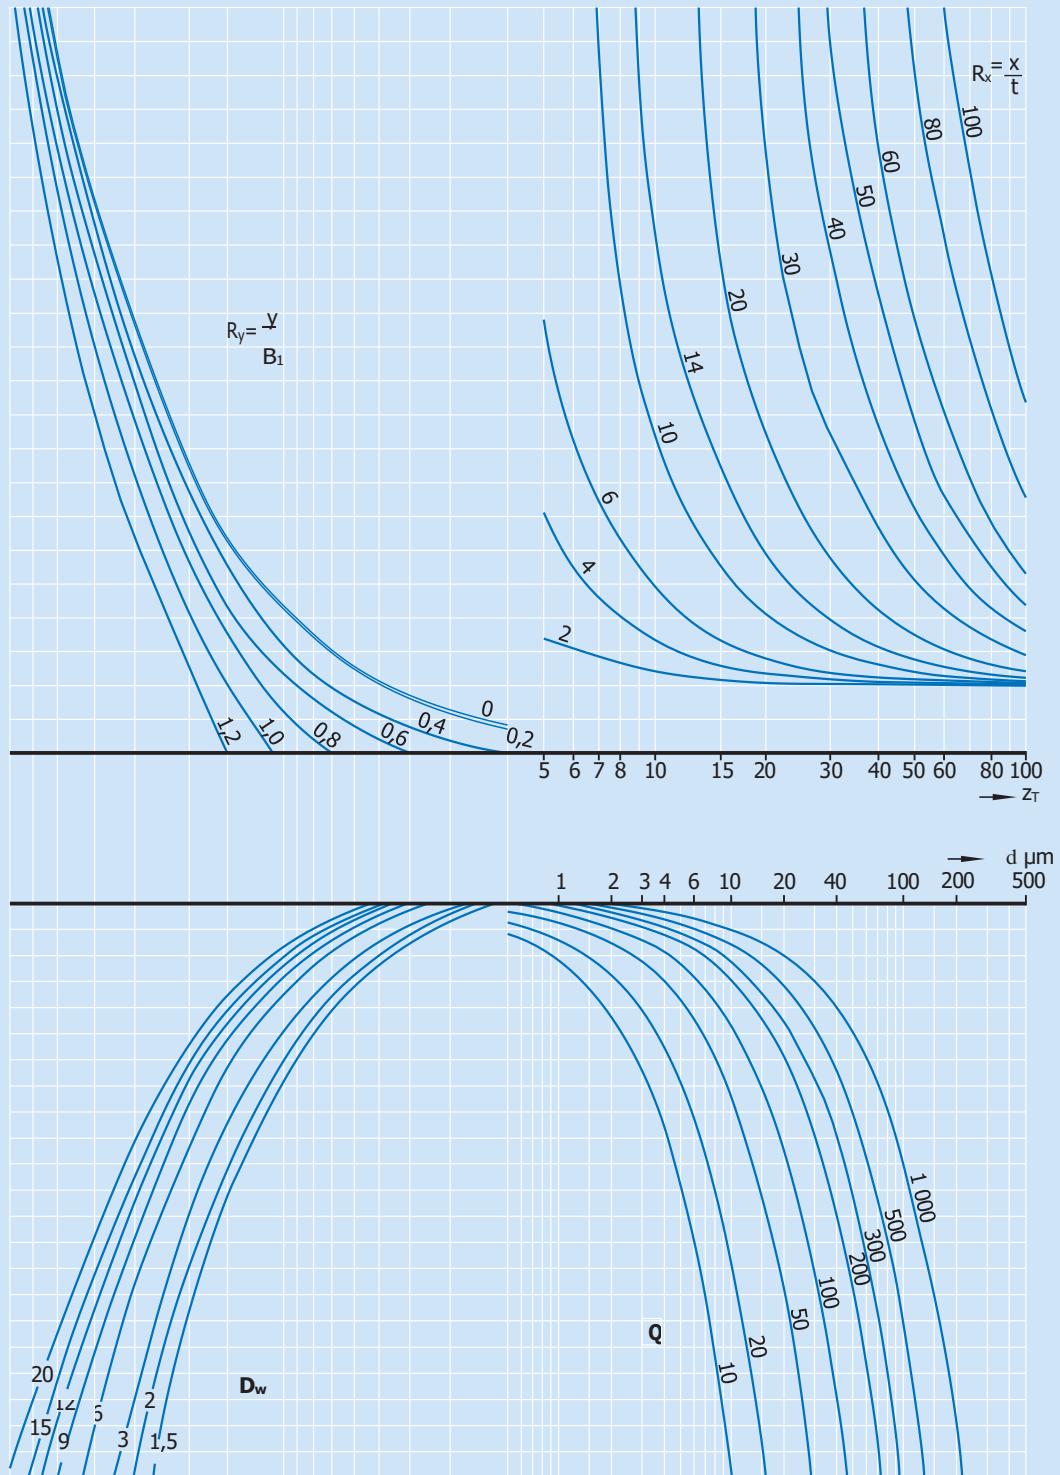

Identify the elastic deformation in the nomogram

The values created in section preparation are now needed to finally identify the elastic deformation d in the nomogram († diagram 8–11).

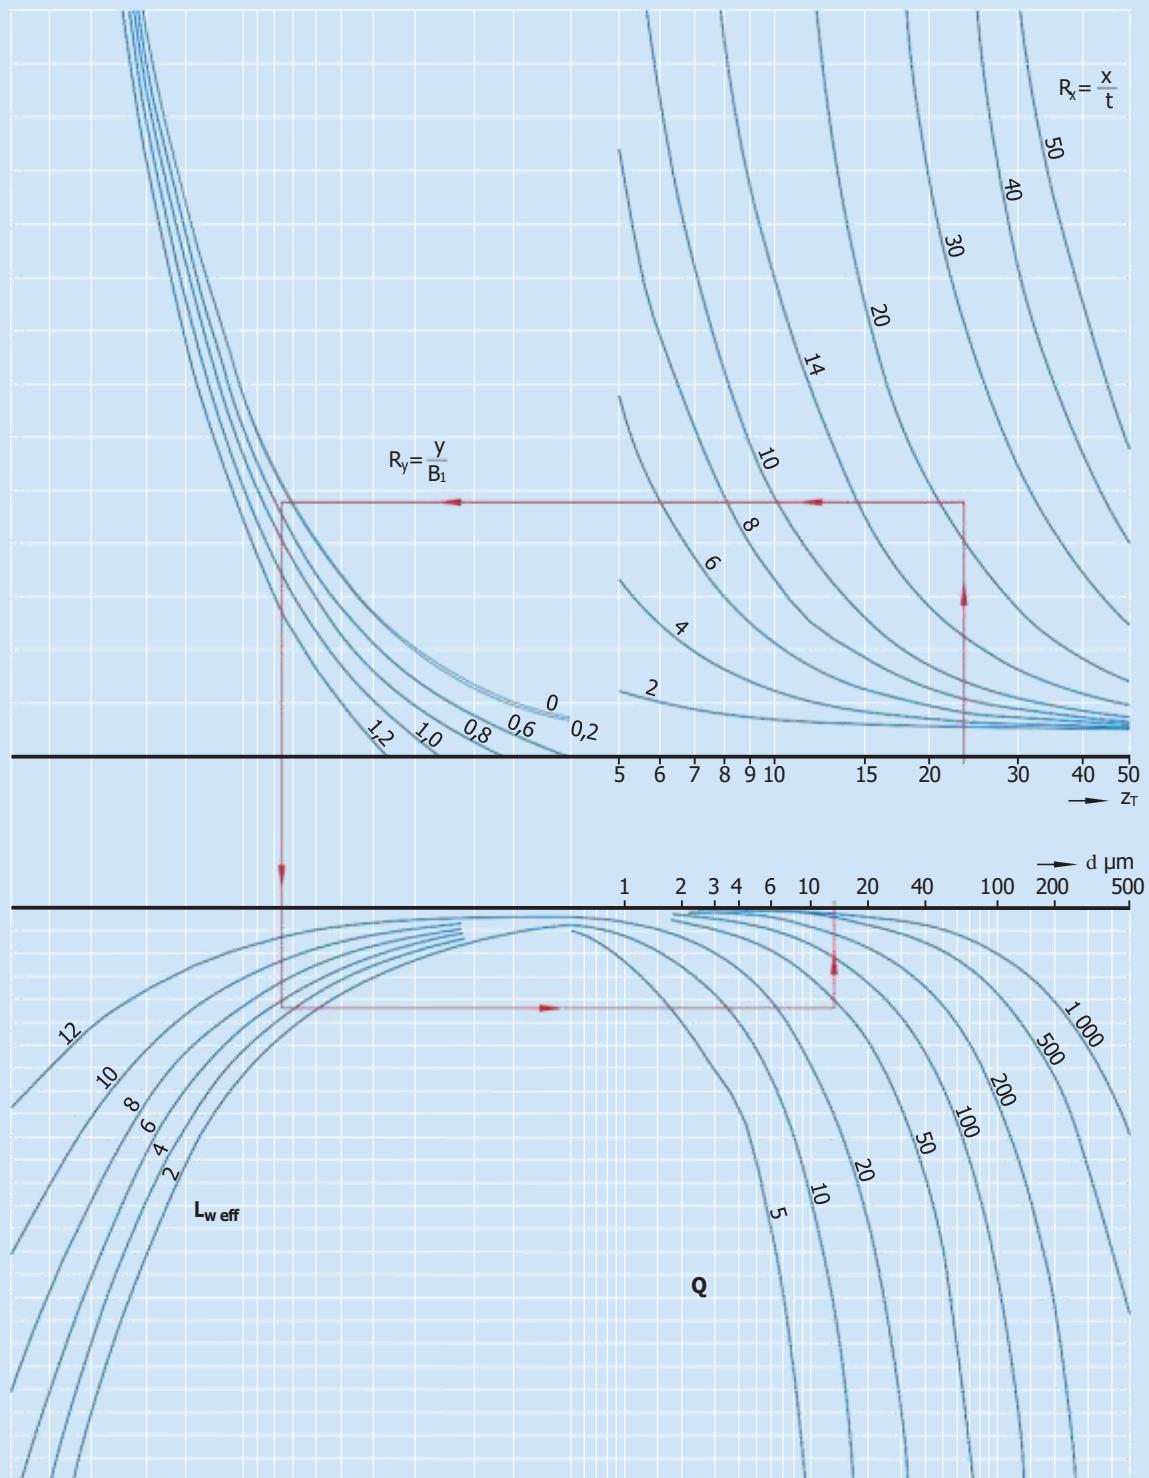

Nomogram of elastic deformation for LWR rail guides with crossed roller assembly

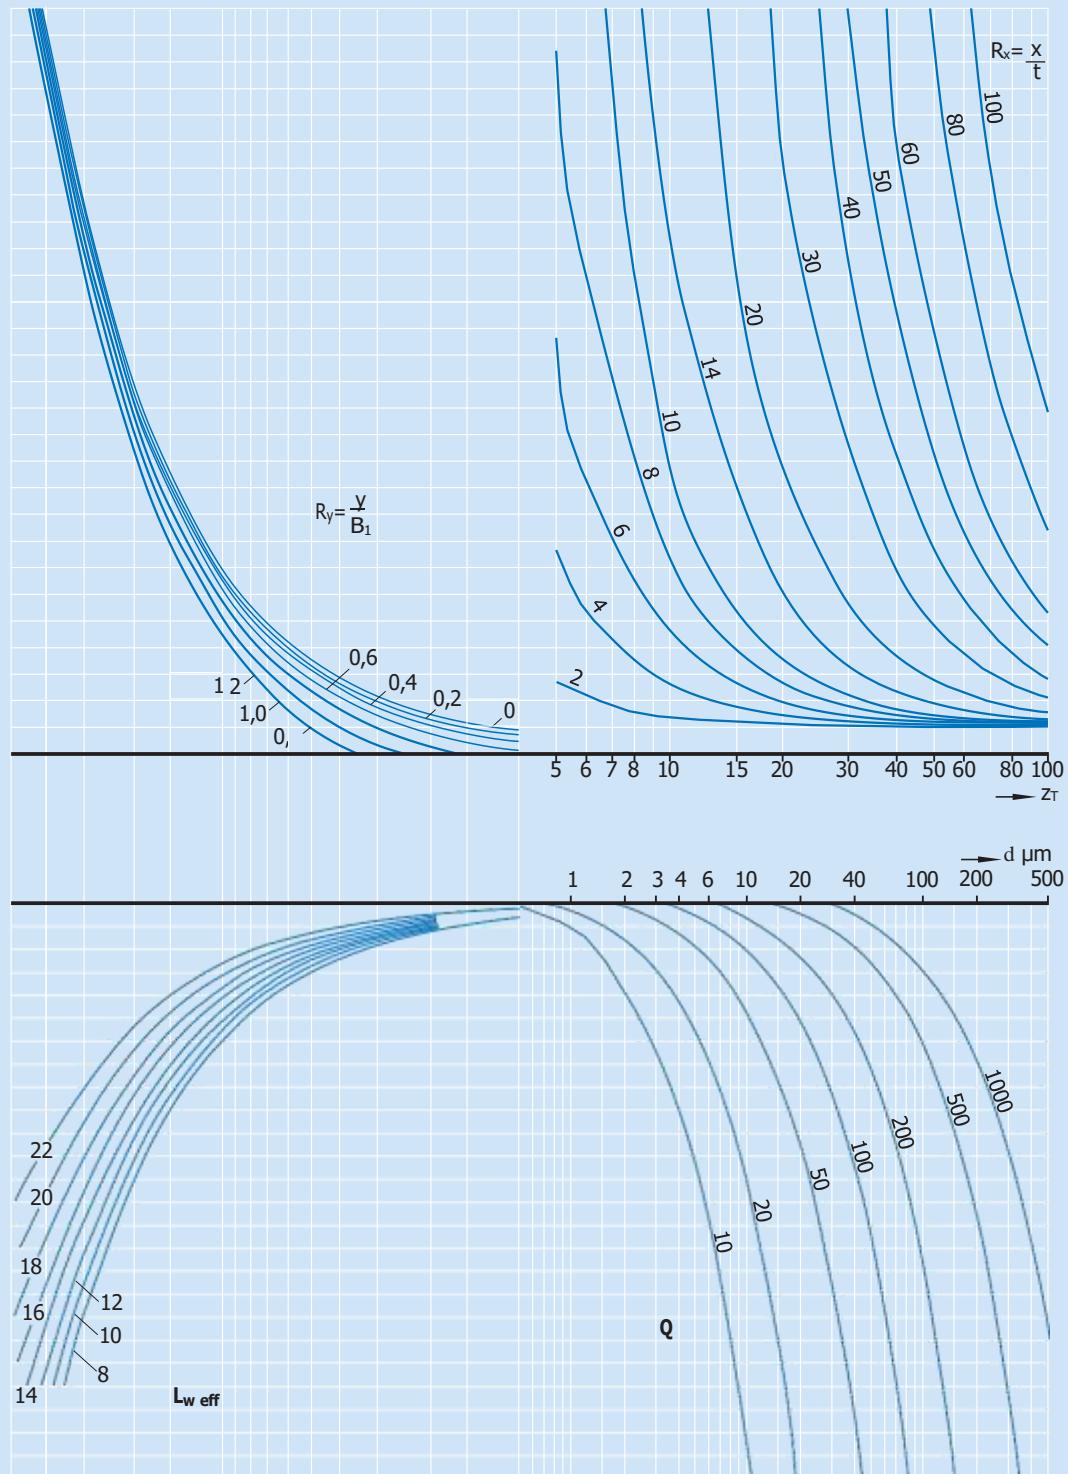

Nomogram of elastic deformation for LWR rail guides with ball assembly

Nomogram of elastic deformation for LWRE rail guides with high capacity crossed roller assembly

Nomogram of elastic deformation for LWRM / LWRV and LWM / LWV rail guides with needle roller assembly

1.11.2 Determination of resulting deflection of a rail guide system

When comparing the measured elastic deflection of a complete slide system with the values of the nomograms, the rigidity of the complete slide system will be found to be significantly less. This discrepancy is mainly due to uneven load distribution along the guide. This happens because inaccuracies of form, deviation from parallelism, improper mounting, etc. and can lead to variations in the loading of the single rolling element along the rail guide. By using factor f_k , which is based on the number of load carrying rolling elements z_T and the specific load on a rolling element k , attention is paid to this circumstances. The relevant values of f_k for LWRE rail guides with crossed roller assembly and LWRM/LWRV rail guides or LWM/LWV rail guides with needle roller assembly can be obtained from **diagram 12**. When calculating the elastic deflection of an LWR rail guide, the correction factor f_k has to be obtained from **diagram 13**. When using LWR rail guides with ball assembly the calculated values conform to the measurements and no factor f_k is needed.

For the calculation example in chapter 1.11.3, both diagrams already contain the values and lines.

Determination of the specific load per rolling element:

for LWR crossed roller assembly:

$$k = \frac{F_z}{z_T D_w^2}$$

for LWRE crossed roller assembly:

$$k = \frac{F_z}{z_T D_w L_{w\text{eff}}}$$

for needle roller assembly:

$$k = \frac{F_z}{2 z_T D_w L_{w\text{eff}}}$$

where

k = specific load per rolling element

[N/mm²]

F_z = single load in z-direction [N]

z_T = number of load carrying rolling elements (per cage or per row for needles)

D_w = rolling element diameter [mm]

$L_{w\text{eff}}$ = contact length of rolling element [mm]

Diagram 12

Correction factor f_k for LWRE, LWRM/LWRV or LWM/LWV rail guides

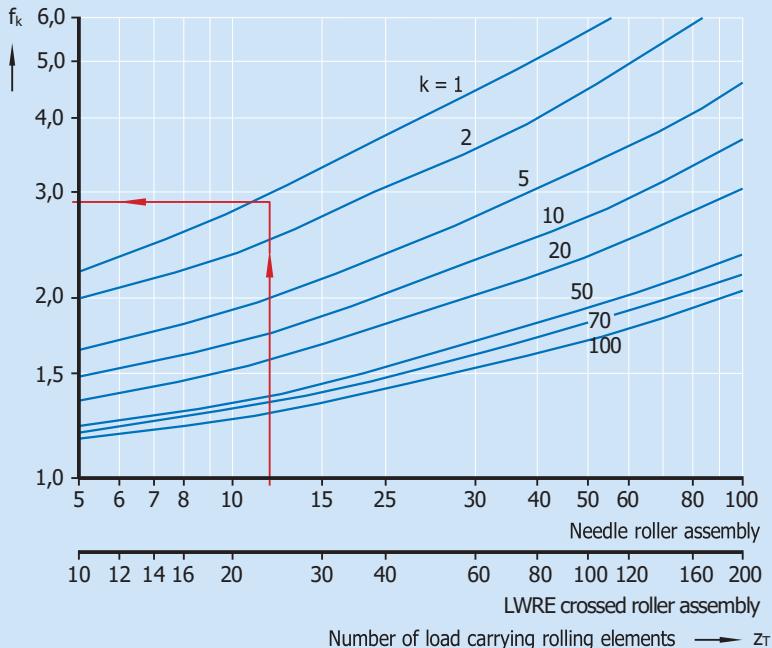

Diagram 13

Correction factor f_k for LWR rail guides

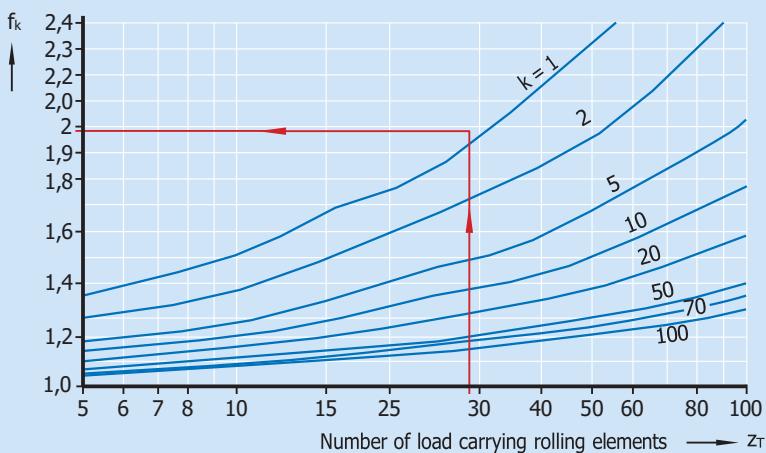

Table 8

Calculation of resulting deflection:

$$d_{\text{res}} = f_k d$$

where

d_{res} = resulting deflection [μm]

d = elastic deformation (determined in nomogram) [μm]

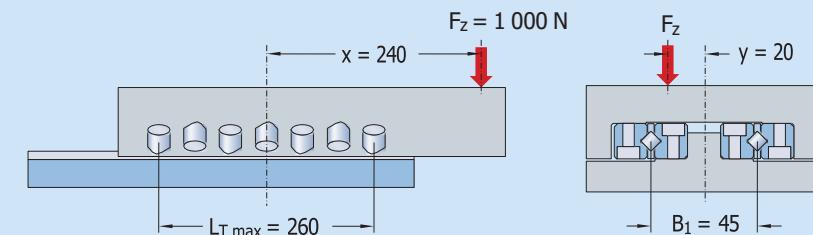

f_k = correction factor

1.11.3 Calculation example for the resulting deflection

The standard SKF GCL 6400 slide is loaded in an extended position with a load of 1 000 N as shown in **table 8**. What is the resulting deflection of the LWR6 rail guide at the point where the load is applied in this case? How great would this have been for a LWRE6 rail guide?

Following values have to be determined (**+ table 8**).

Calculation example for the resulting deflection

Parameter	Unit	LWR	LWRE
Load carrying length L_T	mm	252	253
Pitch of rolling element assembly t	mm	9	11
Number of load carrying rolling elements z_T		29	24
Leverage ratio $R_x = x/t$		26,7	21,8
Leverage ratio $R_y = y/B_1$		0,44	0,44
Rolling element diameter D_w	mm	6	8
Contact length of rolling element $L_{w \text{ eff}}$	mm	2,4	4,7
Average load per rolling element Q	N	34,5	41,7
Elastic deformation d (determined in nomogram)	μm	22,5	13
Specific load per rolling element k	N/mm^2	0,96	1,1
Correction factor f_k		1,99	2,9
Resulting deflection d_{res}	μm	45	38

1.12 Technical data of precision rail guides with slide coating

1.12.1 Surface pressure

To achieve a reasonable value for the contact deformation, the surface pressure of plain bearings or guidings is normally in the region of 0,2 to 1 N/mm². **Diagram 14** shows the surface deformation of Turcite-B rail guides expressed in relation to surface pressure. In case of overload, up to 6 N/mm², the contact deformation rises to 5 µm but recovers to the original dimension when the load is relieved.

1.12.2 Wear

LWRPM / LWRPV rail guides are characterised by their high resistance to wear. The ground surface of the LWRPV guides is matched to suit the Turcite-B so that the degree of wear is kept to a minimum. Even a certain amount of contamination can be tolerated without affecting the sliding qualities since the slide material is capable of allowing small particles to become embedded in the surface.

For optimum performance, however, lubrication of the LWRPM / LWRPV rail guides is recommended. As seen in **diagram 15**, the oil-lubricated guide (curve 1) shows less wear along the length of travel in comparison with the non-lubricated guide (curve 2). The values indicated are for an average surface pressure of 0,4 N/mm².

1.12.3 Frictional properties

Due to the favourable frictional qualities of Turcite-B, the running speed of a dry sliding rail guide has relatively little effect on the coefficient of friction, and 'stickslip' is virtually eliminated.

Diagram 16 illustrates the relationship between the coefficient of friction for LWRPM / LWRPV rail guides as a function of sliding speed. Curve 1 applies to an oil-lubricated guide, and curve 2 applies to a non-lubricated installation. The degree of friction is seen to fall during a 'smoothing' phase and then remains relatively constant. The values indicated are based on an average surface pressure of 0,2 N/mm².

Diagram 14

Contact deformation in relation to surface pressure

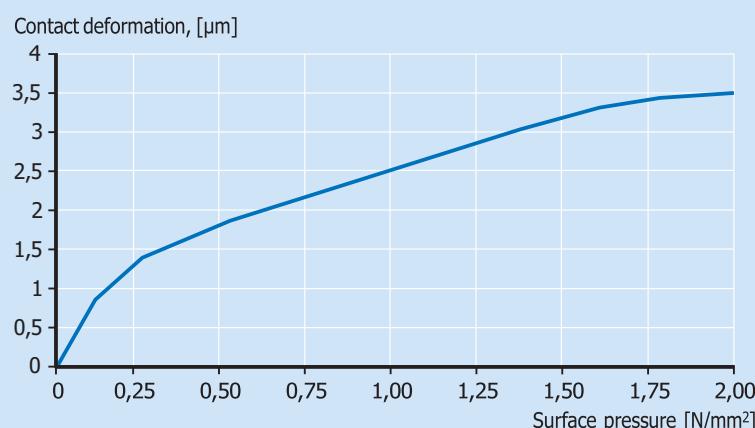

Diagram 15

Wear in relation to length of travel

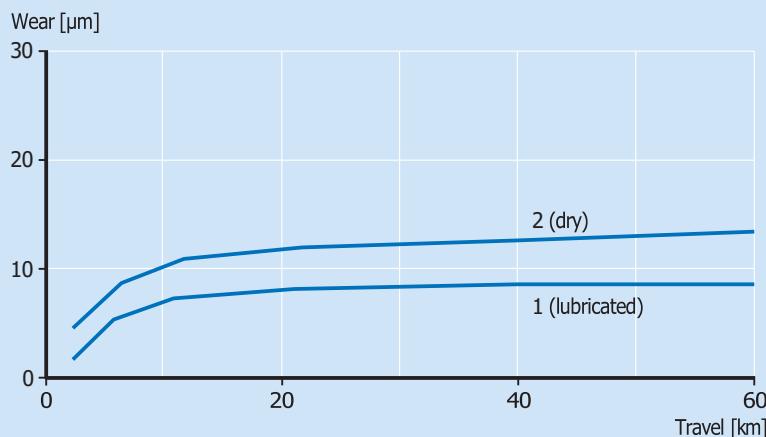

Diagram 16

Coefficient of friction as a function of sliding speed

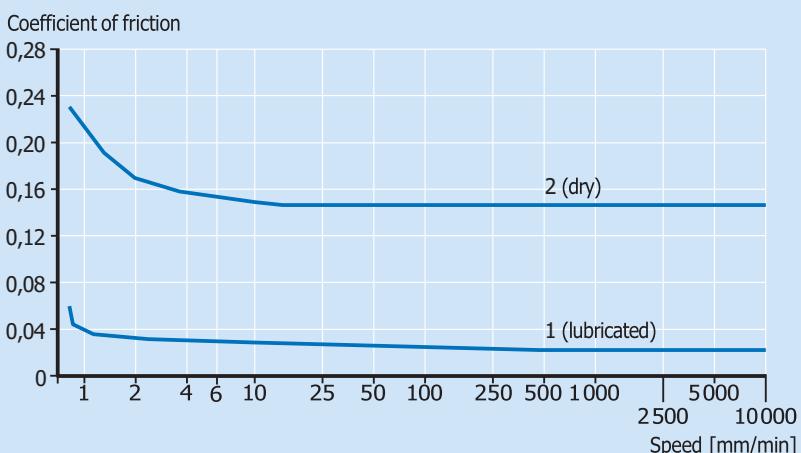

Diagram 17

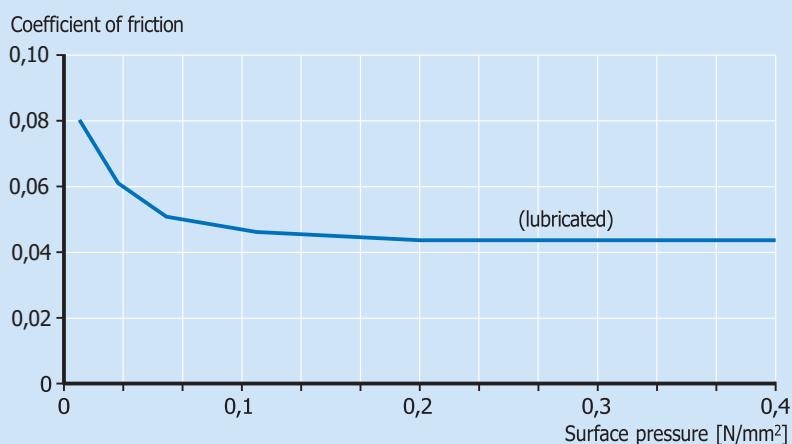

Diagram 17 shows the coefficient of friction for an oil-lubricated LWRPM / LWRPV rail guide in relation to the surface pressure. Here it will be seen that the coefficient of friction for low load conditions is relatively high, but when the surface pressure reaches $0,2 \text{ N/mm}^2$, the coefficient falls to a minimum and remains constant.

1.12.4 Temperature range

The operating temperature of a linear plain bearing should lie between the limits of -40°C and $+80^\circ\text{C}$. Higher temperatures tend to reduce the pressure resistance. In many cases, the dissipation of heat can be enhanced through the use of lubricating oil.

1.12.5 Chemical and humidity resistance

Turcite-B possesses excellent chemical resistance. Moisture absorbency amounts to a maximum of 0,01 percent and has no significant dimensional effect. Sliding surfaces of Turcite-B are consequently highly resistant to cool conditions and the effect of lubricating oils.

Coefficient of friction as a function of surface pressure

S_{tot}	total stroke length	[mm]
X_i, Y_i, Z_i	lever arms that are related to the single loads	[m]
w	rolling element exponent; $w = 0,7$ for balls, $w = 7/9$ for rollers	
Z	number of rolling elements (per cage or per row for needles)	
Z_T	number of load carrying rolling elements (per cage or per row for needles)	

Dimensions from product data:

A	Width of precision rail guide	[mm]
L	thickness of end piece	[mm]
L_1	thickness of end piece with wiper	[mm]
t	pitch of rolling elements in cage	[mm]
t_1, t_2	distance of outer rolling element to the end of the cage	[mm]
t_3	length of anti-creeping system	[mm]
J_1	length between end of rail and first mounting hole	[mm]

Indexes

i	counter for single loads in x-, y- or z-direction that act simultaneously
U	amount of loads that act simultaneously
j	counter for load phases
V	amount of load phases

2 Product data

2.1 LWR / LWRB

Rail guides

LWR and LWRB rail guides are well-proven, limited-travel linear guides used in numerous applications. They can be used with crossed roller assemblies or ball assemblies, depending on the respective application. LWR rail guides with crossed roller assemblies are preferred for high load carrying capacity and good rigidity behaviour. LWRB rail guides with ball assembly can be used where loads are light and/or easy running is required. The small cross-section is ideal for applications with limited space.

Rolling element assemblies

LWJK ball assemblies, which are used together with LWRB rails, are provided with a ball-retaining plastic cage. These are available for sizes 1 and 2.

LWAK crossed roller assemblies comprise a plastic cage with retained cylindrical rollers, available as standard for size 3.

LWAL crossed roller assemblies, consisting of an aluminium cage with retained rollers, are available in sizes 6 to 12.

End pieces

End pieces prevent drift of the cage away from the loaded zone. Available types are LWERA, LWERB as standard end pieces, and LWERC as end pieces with wipers. All end pieces are supplied with appropriate mounting screws.

Ordering example:

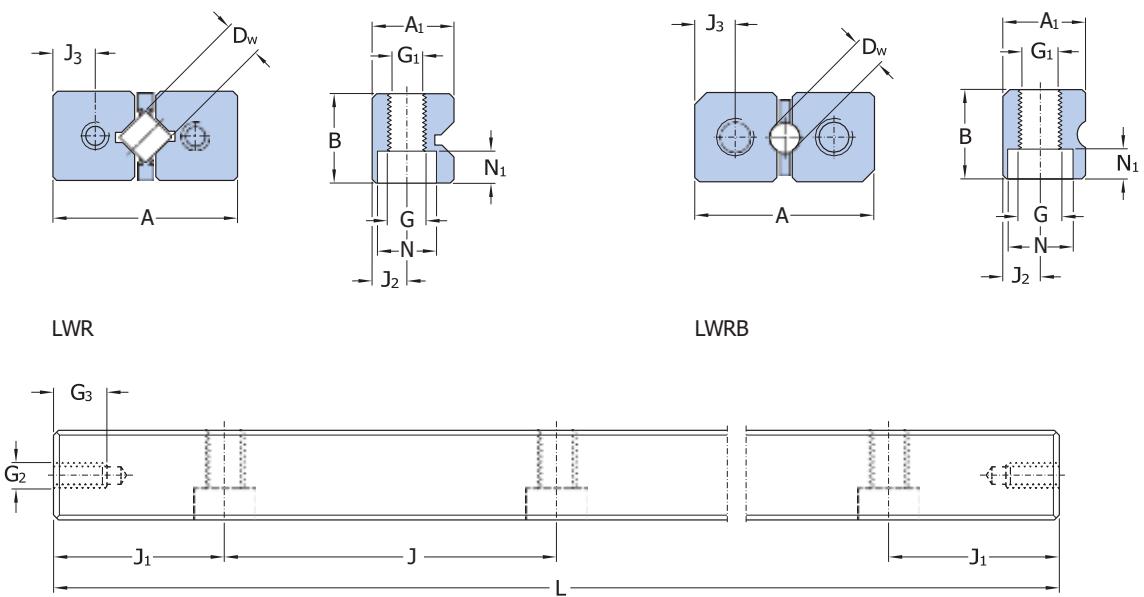

4x LWR 9600

2x LWAL 9x25

8x LWERA 9

2.2 LWRE

Rail guides

LWRE rail guides are a logical development of the proven LWR rail guides. In addition to the familiar characteristics of the LWR series, the LWRE rail guides offer the advantages of fivefold load ratings and a doubling of the rigidity. This means that for the same load capacity, a 50% reduction in bearing size compared with the standard LWR rail guide is possible (**† fig. 1**). Alternatively, with the same outer dimensions, greatly increased static safety and lifetime results.

The improvements are achieved through optimized internal geometry in conjunction with larger roller diameters. Furthermore, LWRE rail guides utilise the whole roller length so that no tilting moment or edge stresses can occur (**† fig. 2**). The mounting and attachment dimensions of the LWRE rail guides conform to those of all the SKF Modular Range rail guides included in this catalogue.

Rolling element assemblies

LWAKE crossed roller cages consist of individual plastic elements. In LWAKE 3, 6 and 9 cages, these elements are assembled using a 'snap in' technique, whereby each element can be rotated manually through an angle of 90° (**† fig. 3**). The load rating and rigidity can be increased by turning the rollers in the direction of the main load. As standard, the orientation of the rollers is alternating. The cage retains the rollers and at the same time almost fills the free space between the rails, thus providing good protection against ingress of dirt. LWAKE 4 cages consist of roller segments fitted together to the customer's specific length requirements. Individual rotating is not possible for size 4.

End pieces

End pieces prevent drift of the cage away from the loaded zone. LWERE end pieces are generally used for horizontal and vertical applications. An end piece with wiper, LWEREC, is available. All end pieces are supplied with appropriate mounting screws.

Ordering example:

4x LWRE 6200
2x LWAKE 6x13
8x LWERE 6

2.3 LWRE ACS

Rail guides

LWRE ACS rail guides are identical to LWRE rail guides, but designed for use with anti-creeping LWAKE ACS cages. The non-slip effect is achieved through a patented control gear attached to the cage, which is in mesh between the LWRE ACS rails during operation, thus retaining the cage in its defined position. As standard, the rails are prepared for maximum stroke (*† chapter 1.4*).

Rolling element assemblies

In principle, LWAKE ACS are the same as LWAKE cages, whereby LWAKE ACS crossed roller cages incorporate an additional control gear located at the centre of the cage. The load carrying capacity of LWAKE ACS cages is also identical with that of LWAKE standard cages, assuming that they comprise an identical number of rollers. However, consider that due to their additional control gear, LWAKE ACS cages are longer than the corresponding LWAKE cages, even if the number of rollers is identical. Overrunning cages should only be used after consulting SKF.

End pieces

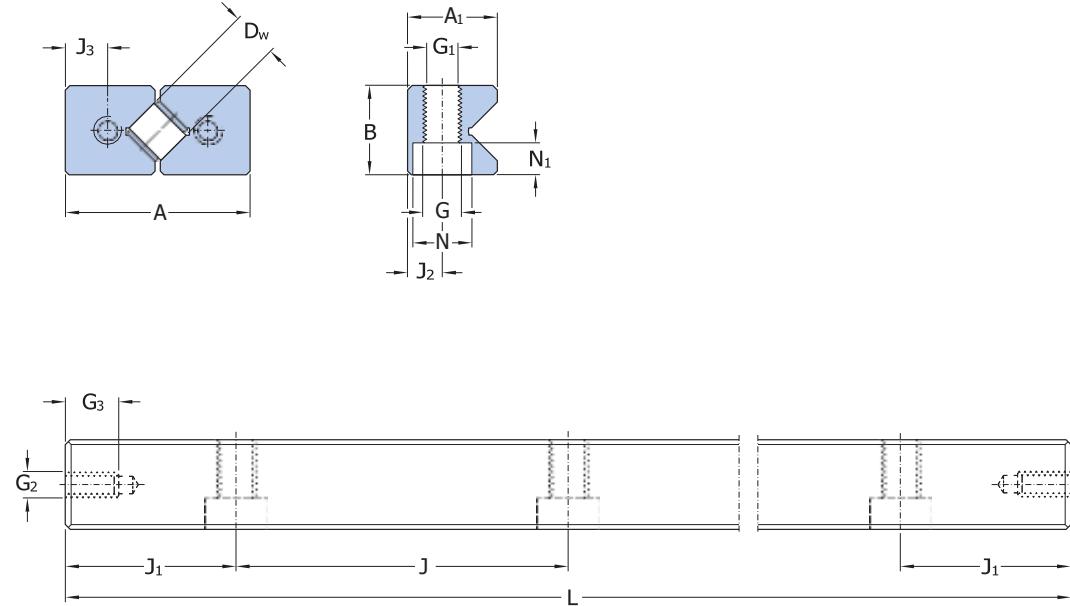

End pieces are generally not needed, but for production reasons, the tapped holes on the rail's end face are standard and end pieces can be mounted. LWERE end pieces are generally used for horizontal and vertical applications. An end piece with wiper, LWEREC, is available. All end pieces are supplied with appropriate mounting screws. The end pieces for LWRE rail guides are also suitable for LWRE ACS rail guides.

Ordering example for rail with maximum stroke:

4x LWRE 6200 ACS
2x LWAKE 6x12 ACS
8x LWERE 6

2.4 LWRE / LWRB ACSM

2

Rail guides

The refinement of our own ACS solution became the LWRE and LWRB ACSM rail guide version. LWRE and LWRB ACSM rail guides have the same outer dimensions as those without ACSM, but are designed for use with anti-creeping LWAKE ACSM cages. This cage, with an involute-toothed control gear made of brass and involute teeth directly machined into the rail, prevent cage-creeping very effectively and are especially suited for applications with high accelerations (*† chapter 1.4*). These rails are made of stainless steel as standard.

Rolling element assemblies

In principle, LWAKE ACSM cages are the same as LWAKE cages, whereby LWAKE ACSM crossed roller cages incorporate an additional control gear made of brass located at the centre of the cage. When defining the cage length, the additional length of the control gear should be considered. Overrunning cages should only be used after consulting SKF. The given load capacities are already calculated for stainless steel rails, which means factor f_h remains at one for calculation of the lifetime.

End pieces

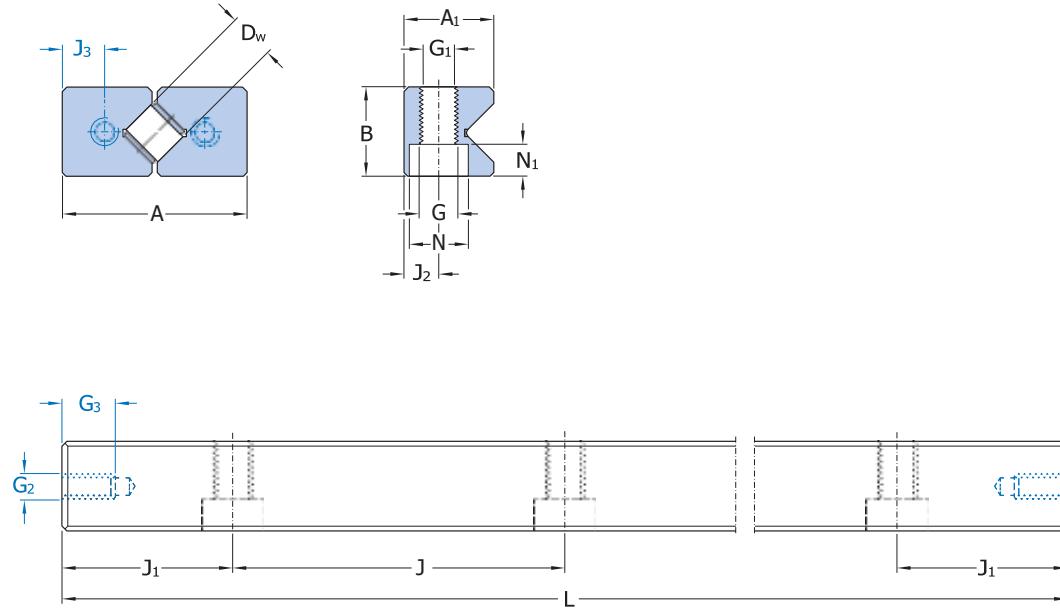

Generally, the LWRE ACSM rail guides are not designed for use with end pieces. However, if required, this must be stated separately in the ordering code of the rail (Option E7). The end pieces for LWRE rail guides are also suitable for LWRE ACSM rail guides.

Ordering example:

4x LWRE 3150 ACSM
2x LWAKE 3x16 ACSM

2.5 LWRM / LWRV

2

Rail guides

LWRM/LWRV rail guides offer guiding systems with high load carrying capacity and maximum rigidity. The mounting and interface dimensions of LWRM/LWRV rail guides conform to those of all the SKF Modular Range rail guides included in this catalogue.

Needle roller assemblies

LWHW needle roller assemblies have aluminium cages with retained needle rollers. LWHV needle roller assemblies consist of a plastic cage with retained needle rollers. They are available for size 6 and 9 units. When ordering, the appropriate cage length in mm should be stated after the cage designation, e.g.: LWHW 10x225.

End pieces

End pieces serve to prevent the drift of the cage away from the loaded zone. Because of the design of LWRM/LWRV rail guides and the respective end pieces, only one rail, the M-shaped or the V-shaped, has to be equipped with end pieces.

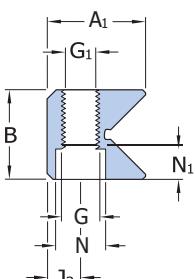

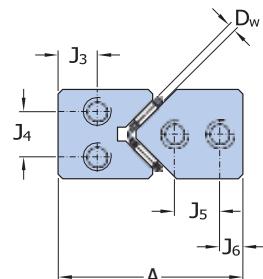

LWEARM and LWEARV end pieces feature a plastic wiper with a sealing lip that keeps the raceways virtually free from contamination. All end pieces are supplied with appropriate mounting screws.

Ordering example:

2.6 LWM / LWV

2

Rail guides

LWM/LWV rail guides enable linear guiding systems to be designed for heavy loads and with maximum rigidity. The internal geometry is identical with that of the Modular Range rails of the LWRM/LWRV series. As the same needle roller assembly is used, the load ratings are also the same. The external dimensions of the LWM/ LWV rail guides differ slightly from those of the LWRM/LWRV Modular Range dimensions. LWM/LWV rail guides are widely used, especially in the machine tool industry. As standard, they are supplied with mounting holes of type 15 (through hole with counter bore). If attachment hole type 13 is ordered, corresponding threaded inserts are supplied with the guide. Hole type 03, directly-machined thread with dimension G, is available on request. For new designs, LWRM/LWRV rail guides are recommended, and offer the advantage of being interchangeable with other rail guides of the Modular Range.

Needle roller assemblies

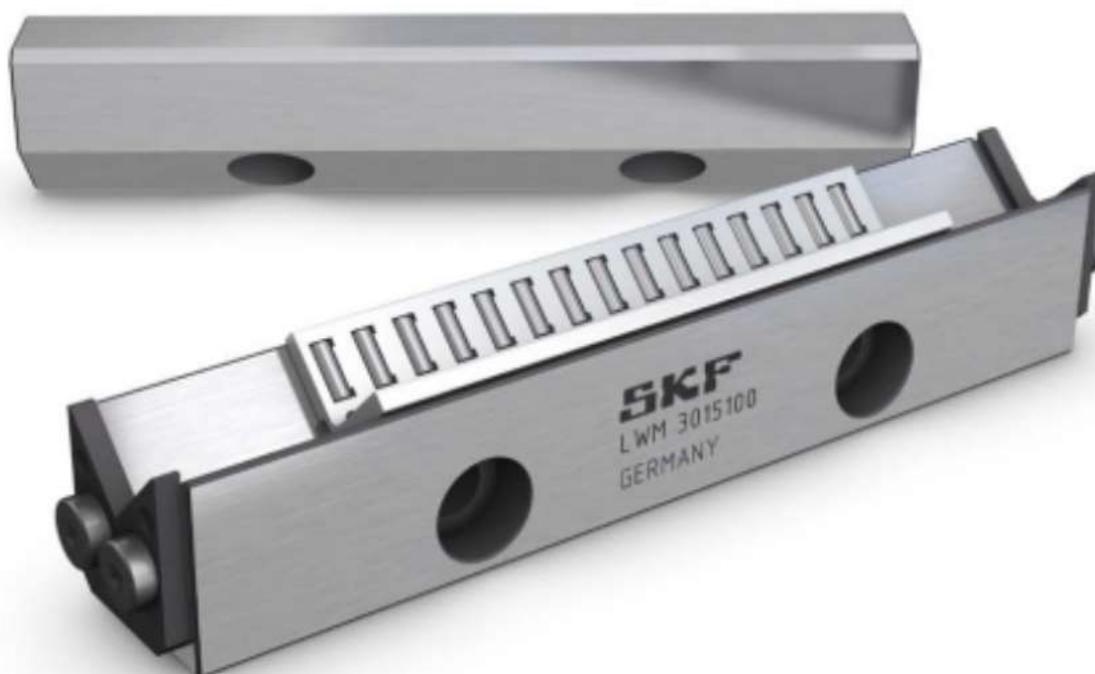

LWHW needle roller assemblies comprise an aluminium cage with needle rollers arranged at right angles to each other. The needle rollers are retained by the cage. LWHV needle roller assemblies, consisting of a plastic cage with retained needle rollers, are available in size LWHV15 and LWHV20.

End pieces for LWM/LWV rail guides

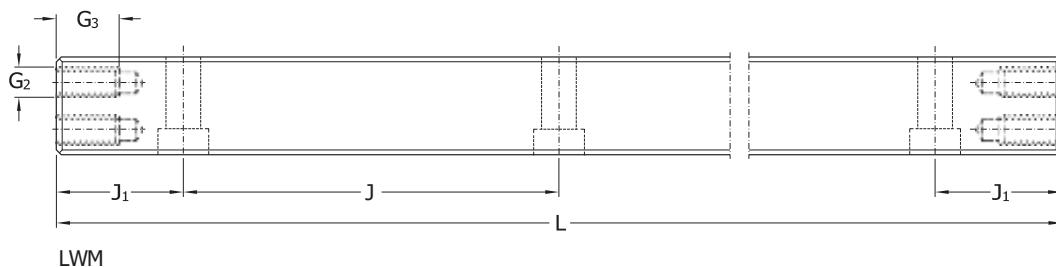

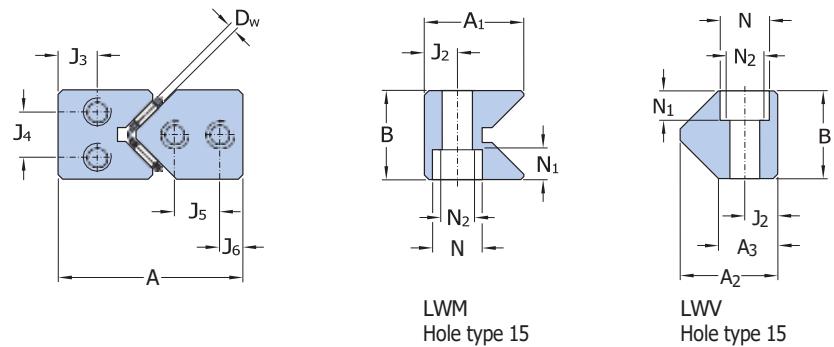

End pieces serve to prevent drift of the cage away from the loaded zone. Because of the design of LWM/LWV rail guides and the respective end pieces, only one rail, the M-shaped or the V-shaped, has to be equipped with end pieces. LWEAM and LWEAV end pieces have the addition of a plastic wiper with a sealing lip that keeps the raceway virtually free of dirt. All end pieces are supplied together with mounting screws.

2.7 LWM / LWV ACSZ

2

Rail guides

LWM / LWV ACSZ rail guides are identical to LWM / LWV rail guides, but designed for use with anti-creeping LWHW ACSZ cages. For this purpose, both rails are equipped with gear racks made of steel. The cage carries two steel control gears that are always in mesh with the racks during operation, and help to ensure the right cage position. As standard, the rails are prepared for maximum stroke, with gear racks over the full rail length († chapter 1.4).

Needle roller assemblies

In principle, LWHW ACSZ are the same as LWHW cages, whereby LWHW ACSZ needle roller cages incorporate two steel control gears located at the centre of the cage. The load carrying capacity of LWHW ACSZ cages is also identical with that of LWHW standard cages. ACSZ does not result in additional cage length. LWHW ACSZ needle roller assemblies comprise an aluminium cage with retained needle rollers.

End pieces

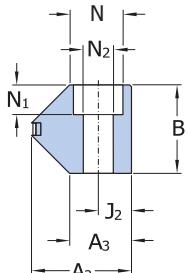

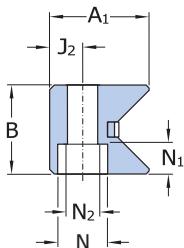

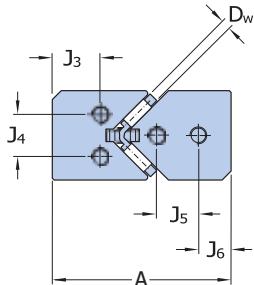

Generally, end pieces are not needed for LWM / LWV ACSZ rail guides, since cage-creeping is prevented by the ACSZ. For production reasons, the tapped holes on the rail's end face are standard, and most end pieces, as for LWM / LWV rail guides, can be used with the exception of LWEAV. If tapped holes on the end face are not required, the rails should be ordered with option "E1".

2.8 LWRPM / LWRPV

Rail guides

LWRPM/LWRPV rail guides are linear guides for limited travel, fitted with Turcite-B slide coating. Based on PTFE, this material is self-lubricating and offers excellent sliding properties. The coating is bonded to the non-hardened LWRPM rail and subsequently ground to size. Separate ordering of the slide coating is not required. The LWRPV rail is hardened and ground. In order to avoid damage to the sliding surface of the LWRPM rail, the LWRPV rail has a lead-in radius as standard. LWRPM/LWRPV rail guides should be used where rail guides with rolling element assemblies are unsuitable due to external influences, for example, extremely short strokes, high impact loads or dusty environment. The mounting and interface dimensions of the LWRPM/LWRPV rail guides conform to those of all the SKF Modular Range rail guides included in this catalogue. More details can be found in chapter "Technical data of precision rail guides with slide coating".

LWRPM/LWRPV rail guides are characterised by:

- Stick-slip-free operation.
- Smooth running.
- Good emergency running properties.
- Low wear and high reliability.
- Resistance to contamination.
- Excellent vibration damping properties.

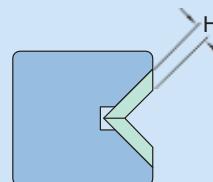

End pieces

LWRPM/LWRPV rail guides normally do not require end pieces. For this reason, tapped holes on the end faces are also unnecessary. However, for production reasons, LWRPV rail guides will, in certain cases, be supplied with tapped holes.

Ordering example:

2 ½ LWRPM 6300
2 ½ LWRPV 6300

LWRPM / LWRPV Slide coating

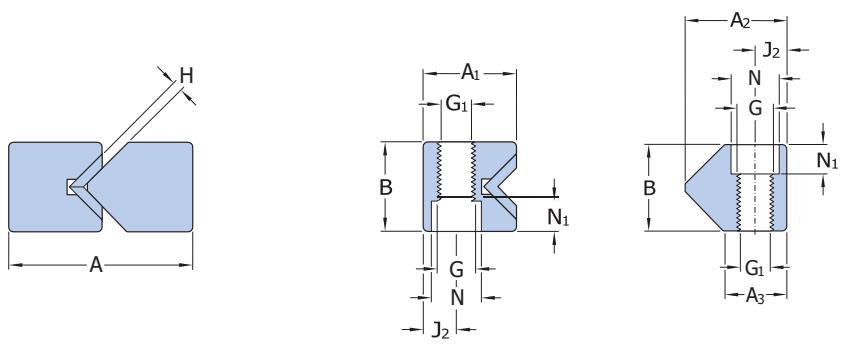

Designation ¹⁾	Dimensions	Load capacity ²⁾
Rail guide	H	C
—	mm	N / 100 mm
LWRPM 3	0,7	300
LWRPM 6	1,7	700
LWRPM 9	1,7	1 200

¹⁾ The slide coating is an integral part of the LWRPM rail and does not have to be ordered separately.

²⁾ For a surface loading of approx. 1 N/mm² (momentary loads of up to 6 N/mm² are permissible).

2.9 Other products

Besides the standard product range, on request SKF can offer additional cages and guiding types, such as flat rail guides or wrap-around guidings. Also, completely customized guidings can be manufactured for applications that do not allow the use of standard products.

2.9.1 LWML / LWV

The LWML rail guide consists of a modified LWM rail guide with the addition of an integrated adjustment wedge (*† chapter 3.1.10, fig. 6*). Used in conjunction with an LWV guide and a needle roller assembly, this provides a preload-adjustable guide system. Inclination of the wedge surface is 1,5%, so that a displacement of the wedge by 1 mm brings about a 15 µm alteration in the height. LWML rail guides are available in classes P10 and P5. When ordering, it should be specified whether the preloading threads are right-hand or left-hand threads.

2.9.2 LWN / LWO

LWN/LWO rail guides differ from the LWM/LWV rail guides only in height, width and attachment holes. The internal geometry of the two rail guide series is the same and their load ratings are identical. LWN/LWO rail guides are available in precision classes P10, P5 and P2.

Customised guidings

With the knowledge and manufacturing capabilities existing within SKF, it is possible for SKF to produce completely customized guidings or other precision parts.

2.9.3 LWJ / LWS flat rail guides

LWJ/LWS flat rail guides are used in conjunction with LWRM/LWRV, LWM/LWV or LWN/LWO rail guides as non-locating linear guides. They are incorporated in floating slides. LWJ/LWS flat rail guides, as well as the appropriate rolling element assemblies and end pieces, are available on request.

2.10 GCL / GCLA standard slides

GCL and GCLA are pre-assembled slides made of steel or aluminium, and crossed roller precision rail guides for applications that require maximum accuracy and rigidity. Typical applications are factory automation, printing, packaging and general machinery. GCL and GCLA standard slides are available on request.

Advantages:

- Top and base plate of a GCL are made of blackened steel or cast iron (depending on size) or aluminium for GCLA.
- Standard patterns of attachment holes for easy mounting.
- Upper and lower mounting surfaces are ground for high running accuracy.
- Reference edge parallel to the slide axis (opposite of preload set screws).
- Internal end stops to limit the stroke.
- Very low friction of the rail guides.
- Relubrication identical with precision rail guides, (*† chapter 3.3*).

2.11 LZM miniature slide

With the LZM miniature slide product range, SKF offers the ideal solution for linear motion applications with short strokes and compact boundary dimensions. The use of miniature slides has significantly increased in medical applications, measurement technologies and micro mechanics and assembly.

The various LZM miniature slide components are designed to meet the highest precision standards. LZM miniature slides feature high running accuracy and smooth motion, and are manufactured with all-stainless-steel components. The maximum value for parallelism between the raceways and the mounting surface is 3 µm. Optimized hardness enables long service life and high performance within compact boundary dimensions.

Ease of installation is another positive feature of LZM miniature slides. Unlike crossed roller systems using 4 rails and 2 cages to be assembled on the production floor, the LZM miniature slide provides a complete slide that can simply be bolted into place without the use of precision devices to set preload.

Customized miniature slides are also possible, and SKF will modify existing designs to meet specific technical requirements. Wide versions of LZMs for higher torque loads can also be supplied on request. Wide versions of LZMs for higher torque loads, comparable with wide miniature profile rail guides LLMWS, can also be supplied on request.

Applications:

- Pneumatics
- Semi-conductor manufacturing
- Medical
- Micro- and electronics assembly
- Measurement applications
- Fibre optics

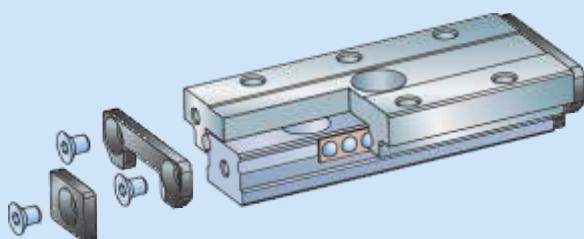

Advantages:

- Compact design
- High load capacity
- Very good running accuracy
- Smooth running
- High rigidity
- Easy assembly

Ordering example

- LZMHS 9 – 26
(P5, T0 as standard – no need to specify)
- LZMHS 9 – 26 T2 P1

LZM data**LZM technical data**

Design	Four point contact with identical load angles
Standard range	Four sizes: 7, 9, 12 and 15
Optional range	Wide versions for 9, 12 and 15
Operating temperature	-20 up to +80 °C
Max. speed	3 m/s
Max. acceleration	80 m/s ² (for preloaded LZMs)

3 Recommendations

3.1 Design rules

3.1.1 Designated use

- SKF precision rail guide systems must only be used for linear movement of loads that do not give off emissions which could pose a danger to the system, and that do not overload the rail guides.
- SKF precision rail guide systems must not be used in outdoor, wet or explosive areas.
- End pieces must not be used as a mechanical stroke limitation of the rail guide system, as this can result in cage damage.

3.1.2 Typical mounting – clamped arrangement

The most common way to design a precision rail guide system is the clamped arrangement, as it has several advantages. Alternatively or for other designs the floating arrangement exists. Both versions are explained more detailed in chapter 1.8.4.

3.1.3 Accuracy of mounting surfaces

An important criteria for correct performance of a rail guide system is accuracy of the mounting surfaces. The higher the demand for accuracy of the guidings and for smooth, easy operation, the greater is the requirement for accuracy of form and position of the counterparts. Values for surface roughness, perpendicularity and parallelism of the mounting surfaces are shown for each precision class in **fig. 1** and **table 1**.

The values for perpendicularity are given in relation to the relevant height of the mounting surface. To ensure an even load distribution over the full length of the rolling element, the maximum difference in height of the mounting surfaces should not exceed Δh .

$$\Delta h = 0,1 \pm B_1$$

Δh = maximum height deviation [μm]

B_1 = mean distance between rolling element assemblies [mm]

Fig. 1

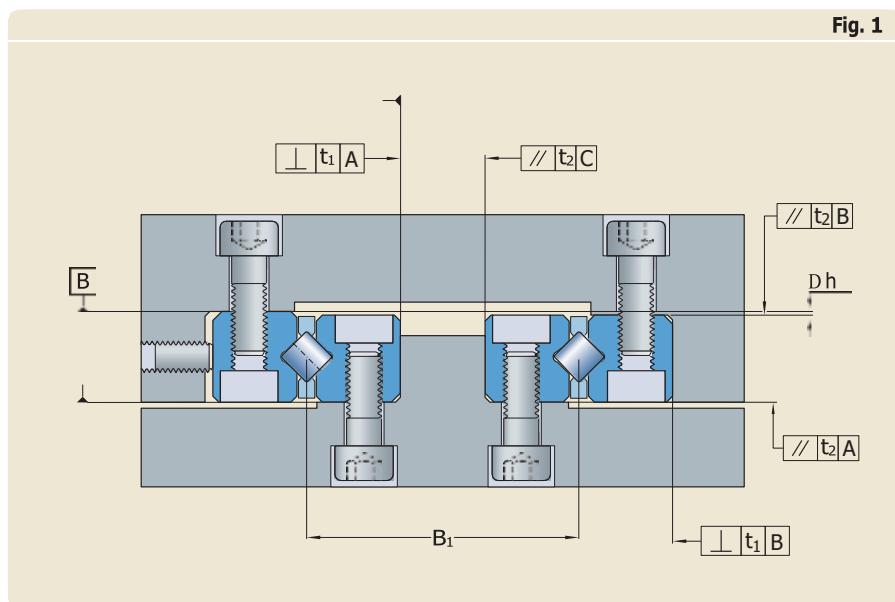

Table 1

Accuracy of form for mounting surfaces						
Characteristic	Symbol	Tolerance	Dimension	Permissible form-deviation for precision class		
				P10	P5	P2
Roughness R_a	▽		μm	1,6	0,8	0,2

		t_2	μm	6	4	2
		t_2	μm	10	6	3

3.1.4 End pieces logic

Together with the different kinematics, also the end pieces have to be selected accordingly. **Table 2** shows the logic.

Table 2

So end pieces mountable by customer. without end pieces

 Can not be changed

 Can be changed on request

3.1.5 Chamfers on the precision rail guides

For the design of surrounding parts, the tolerance of the chamfer between the two reference surfaces of the precision rail guide must be taken into account. The value c is depending on the rail width B († **fig. 2**).

Rail width $B \leq 8$ mm: $c = 0,4$ mm

Rail width $B > 8$ mm: $c = 0,7$ mm

3.1.6 Tolerance of distance between mounting holes

The tolerance of distance between the mounting holes depends on the rail length L_{rail} , which has an impact on possible thermal expansion during heat treatment. The values shown below are valid for all mounting holes along the rail. Rails with tighter tolerances for the distance between the holes can be supplied on request. For long rails, the use of special mounting screws (LWGD) is recommended († **fig. 3**).

$L_{\text{rail}} \leq 300$: $t = 0,6$ mm

$L_{\text{rail}} > 300$: $t = 0,0016 \text{ mm} \pm L_{\text{rail}}$

3.1.7 Calculation of J_1 dimension

Usually the J_1 dimension is chosen symmetrically on both rail ends. If so, the symmetric J_1 dimension can be calculated with the following formula. The minimum of $J_1, J_{1 \min}$, is stated in the product tables and has to be taken in consideration.

If an unsymmetric J_1 dimension is needed it can be stated in the ordering code by using the definition of J_1 as shown in figure "J₁ unsymmetrical" († **fig. 4**).

$$J_1 = \frac{L-SJ}{2}$$

Fig. 2

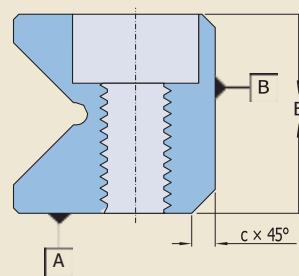

Fig. 3

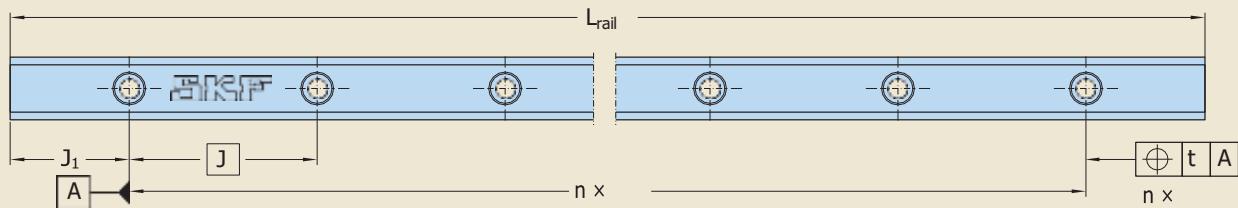

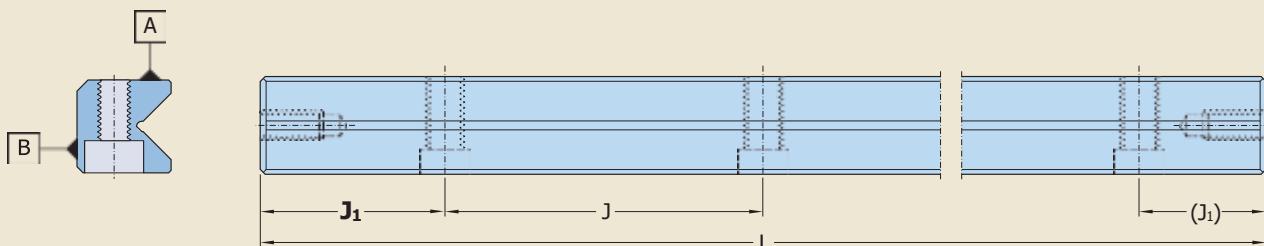

Fig. 4

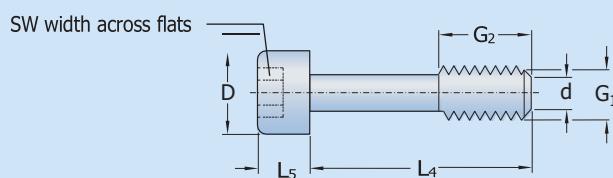

3.1.8 Special mounting screws LWGD

Special mounting screws LWGD help to compensate for manufacturing tolerances. The screw strength class is 8.8. All dimensions are given in († **table 3**).

Table 3

LWGD special mounting screws

¹⁾ other sizes are available on request.

3.1.9 Preloading

Precision rail guides with rolling elements and in clamped arrangement should always be mounted without clearance and thus with a certain preload. Preloading enhances the rigidity of the system as well as the running accuracy. Peaks of load at the end of the cages, caused by torque load M_y and M_z are consequently decreased.

The magnitude of the adjustable preload depends on the actual application and can be up to 20% of the dynamic load carrying capacity of the rail guide. The presence of preload means that the load acting on the rolling elements must be reduced, and this should be taken into consideration when the operating conditions require high preload. Associated components need corresponding stiffness.

Rail guides can be preloaded in many ways. Some examples are shown in († fig. 5 to 7). The most common method is the use of set screws for adjustment. The number of these screws should at least be equal to the mounting holes in the rail. Experience is needed to use this method successfully, in order to avoid "pinching" the rail assembly. **Table 4** gives approximate values for a good running precision rail guide system with a balance of rigidity and friction.

Preloading of rolling assemblies with any ACS system is done using the same values.

The use of adjustment bars or adjustment wedges is recommended in cases where large preloads are required or where high demands are placed on running accuracy. For needle roller cages, SKF can offer the LWML rail, which is equipped with a built-in adjustment wedge.

3.1.10 Tightening torques for mounting screws

Depending on the material of the adjacent components and the screw size, different values of tightening torques have to be used for mounting a precision rail guide († **table 5**). Given values are also valid for the special mounting screws LWGD.

3.2 Mounting

3.2.1 Important requirements

The following instructions describe the mounting procedures for a SKF precision rail guide system. Read these instructions carefully before starting the installation process. Skill and cleanliness are essential when mounting precision rail guides, to obtain optimum performance and to avoid mounting-induced bearing failure. Mounting should be carried out in a dry, dust-free room away from metal-working machines and other machinery producing swarf or dust. Prior to mounting the rail guides, all necessary parts and equipment should be at hand. Appropriate tools and measuring devices are to be used at all times. Rail guides are precision products and should be handled with due care. Not following these instructions could reduce system service life or create a safety risk.

3.2.2 General mounting rules

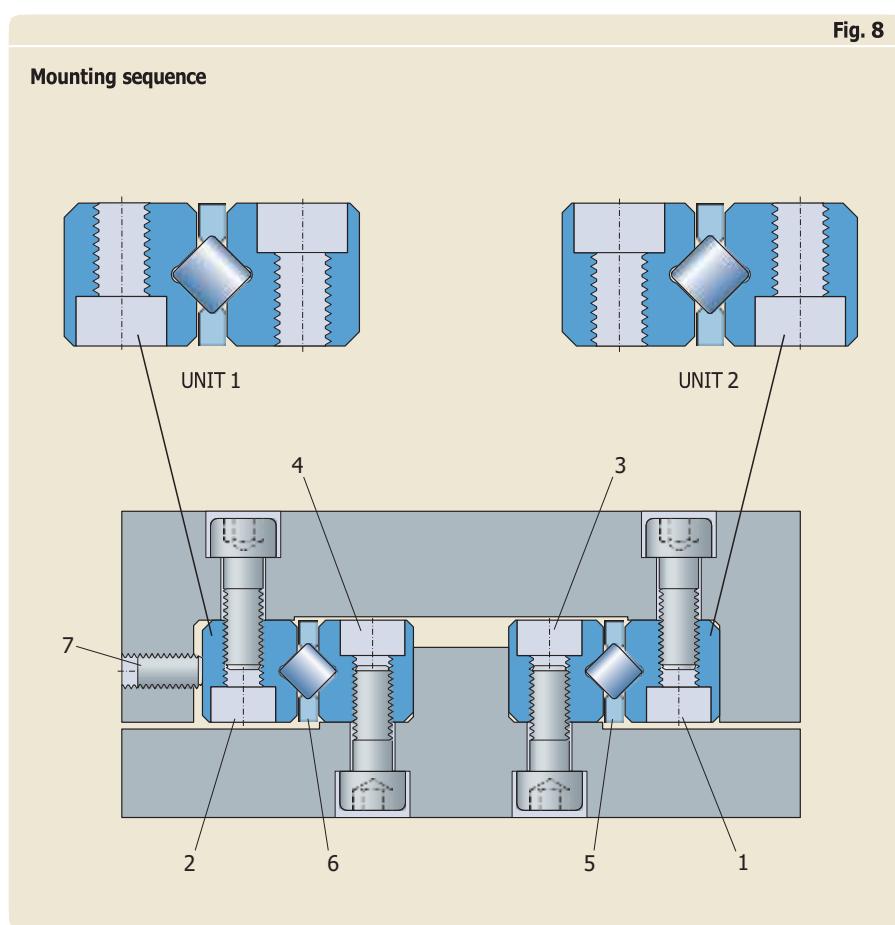

All parts of the linear guiding system should be carefully cleaned and deburred and the accuracy of form and dimension of all adjacent components checked against the specification, († chapter, 3.1.3). The rails should not be removed from their original packaging until immediately before mounting, to minimise the risk of contamination. After unwrapping, the corrosion inhibitor has to be removed. When using SKF LGEP2 grease, the corrosion inhibitor can remain on the raceways. The reference surfaces of the rails and the mounting surfaces of the adjacent parts should be carefully cleaned and lightly oiled to prevent contact corrosion during operation. The reference surface A is generally on the opposite side of the SKF label. Apply the chosen lubricant onto the raceways and the rolling element assemblies prior to mounting.

NOTE: To retain the high performance of precision rail guides, it is recommended not to mix rails of different packages (compare chapter 1.6.12).

3.2.3 Mounting of rail guides without Anti-Creeping System

Mounting of a rail guide in a clamped arrangement should take place in the following sequence (**fig. 8**):

- 1 Inner rails 3 and 4 are pressed against the mounting surfaces and bolted down, applying the prescribed torque.
- 2 Fixed rail 1 is pressed against the mating mounting surfaces and bolted down, applying the prescribed torque.
- 3 The outer rail 2 is pressed onto its counterpart and bolted lightly in position.
- 4 The lubricated cages 5 and 6 are moved to their desired position (usually centred).
- 5 The outer rail 2 is used for preload adjustment because a system in clamped arrangement has to be operated with zero clearance or with preload, depending on the application. The preload is adjusted by means of set screws 7 with the help of a torque wrench. For the correct adjustment sequence, follow the numbers on the set screws as described in **Fig. 9**. Be sure to tighten the set screws from inside to outside, and have rolling elements underneath the corresponding set screws. Recommended tightening torques, which should only be considered as approximate values, are given in **table 4**, chapter 3.1.9.
- 6 The fixing bolts on the outer rail 2 are tightened by applying the prescribed torque.
- 7 The running accuracy of the slide assembly is checked.
- 8 The end pieces, if applicable, are mounted.
- 9 The external end stops of the slide assembly are mounted. The rolling element assemblies should not be used as counterparts for the end stops.

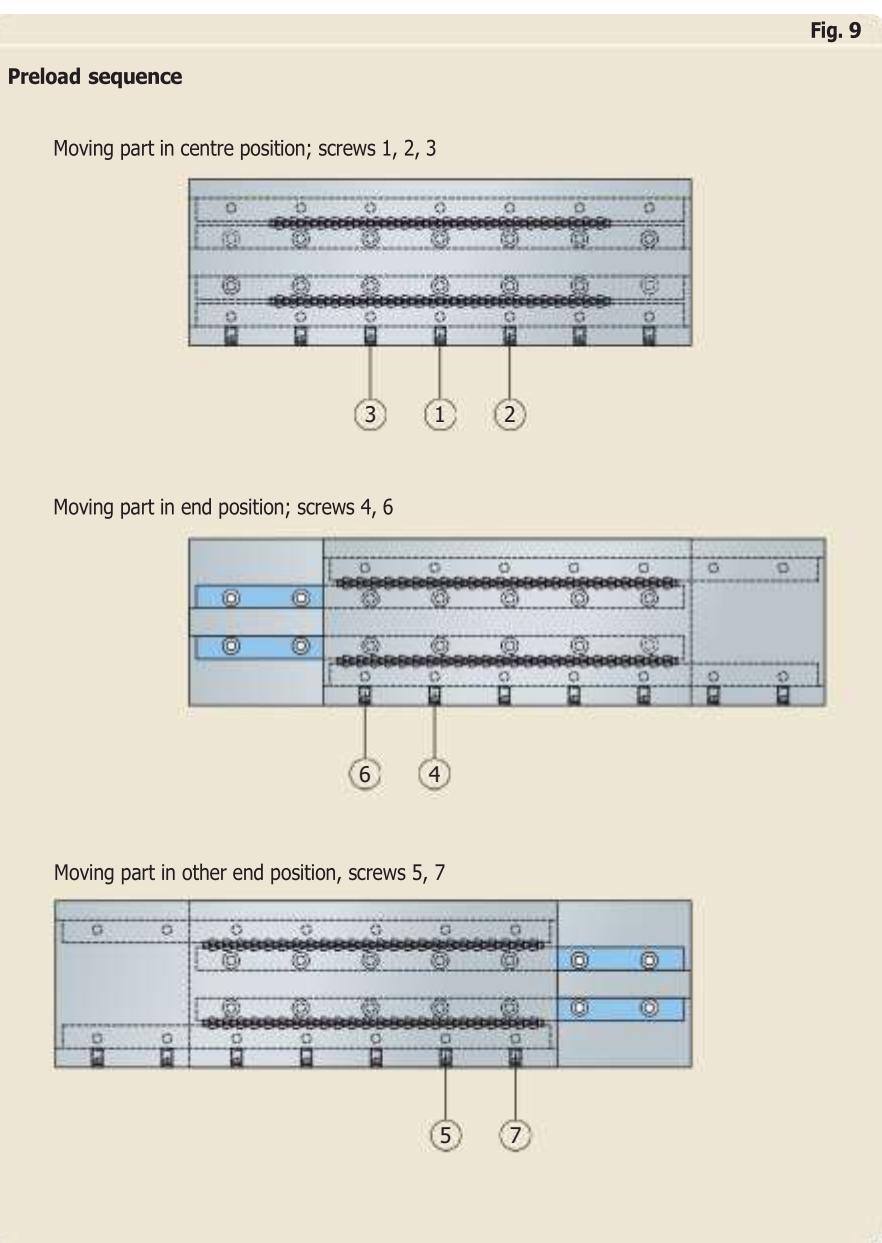

3.2.4 Mounting of rail guides with Anti-Creeping System

In order to avoid damage to the Anti-Creeping System, the rails have to be mounted as pre-assembled units with the cages correctly positioned. Any direct or indirect force subjected to the ACS control gear will damage it.

The following instructions are valid for all types of Anti-Creeping Systems (ACS, ACSM, ACSZ).

- 1 Outer rail 1, inner rail 3, and lubricated cage 5 are put together as unit 1 with the cage in its correct position – typically centred.
- 2 Unit 2 should be prepared in the same way by using inner rail 4, outer rail 2 and cage 6.
- 3 Both units are pushed in to the desired position between the bottom and top part from the front side.
- 4 Unit 1 is pressed against the mounting surfaces and bolted down, applying the prescribed torque.
- 5 Inner rail 4 is pressed against the mating mounting surfaces and bolted down, applying the prescribed torque.
- 6 Outer rail 2 is mounted onto its counterpart, and bolted lightly in position.
- 7 The outer rail 2 is used for preload adjustment because a system in clamped arrangement has to be operated with zero clearance or with preload, depending on the application. The preload is adjusted by means of set screws 7 with the help of a torque wrench. For the correct adjustment sequence, follow the numbers on the set screws as described in **fig. 9**. Be sure to tighten the set screws from inside to outside and have rolling elements underneath the corresponding set screws. Recommended tightening torques, which should only be considered as approximate values, are given in **table 4**, chapter 3.1.9.
- 8 The fixing bolts on the outer rail 2 are tightened by applying the prescribed torque.
- 9 The running accuracy of the slide assembly is checked.
- 10 The end pieces, if applicable, are mounted.
- 11 The external end stops of the slide assembly are mounted. The rolling element assemblies should not be used as counterparts for the end stops.

3.3 Maintenance

3.3.1 Lubrication

SKF precision rail guides usually require very small quantities of lubricant. Both grease and oil can be used. Lubricants with solid additives, or grinding emulsions and coolants are unsuitable.

Under normal operating conditions, grease is generally used to lubricate rail guides. Compared to oil, grease is more easily retained in the bearing arrangement, particularly where the rail guides are mounted in an inclined or vertical position. Grease also contributes to the sealing of the rail guide against contamination and humidity.

Since rail guides, particularly in low speed applications, operate almost exclusively under borderline or mixed friction conditions, the use of grease with extreme pressure (EP) additives is advisable. SKF recommends using SKF bearing grease LGEP2. This grease is based on lithium soap and mineral oil. It has excellent water repellent and corrosion resistance properties and can be used in the temperature range -20°C to $+110^{\circ}\text{C}$.

Oil lubrication is often employed in situations where neighbouring machine components are oil lubricated, or where high speeds of travel are involved. A simple method of lubrication with oil is the oil drop method. Ordinary mineral oil with EP additives and viscosities in the range of ISO VG 45 to 200 is suitable.

Lubricant can be supplied to the rail guides most easily using the lateral gap between the rails. If this is not possible because of the design of the arrangement, rails provided with lubrication holes can be supplied, in which case a drawing should be forwarded to SKF, indicating the size and location of the holes. It is also possible to connect central lubrication units, which can be offered by SKF. Be aware that the ACS control gears and its axis must also be lubricated.

3.3.2 Relubrication interval

There are no general rules given for re-lubrication intervals for precision rail guides, as these must be individually determined for each application. However, we recommend re-lubricating at least once a year.

3.3.3 Repairs

If a precision rail guide system has reached the end of its service life and needs to be replaced, SKF recommends replacing the complete system. When re-ordering, please identify the size, rail length, J1 dimension (distance from rail end to first mounting hole), hole type and cage length / stroke.

3.3.4 Stationary conditions / shipping / storage

If a precision rail guide is stationary for long periods and subjected to vibration from external sources, micro movement in the contact zone between rolling elements and raceways will lead to damage of those surfaces. This damage can result in a significant increase in running noise, and premature failure due to material fatigue. Damage of this kind should be avoided at all costs, for instance by isolating the bearings from external vibration and by taking suitable precautions during transport.

03 threaded hole

10 through hole

13 threaded inserts integrated in the rail (only LWM and LWV)

15 through hole with counterbore (standard at LWM and LWV, no code needed)

J₁ dimension in mm

No code standard, symmetrical J₁ on both ends

Value unsymmetrical J₁ in mm; definition († chapter 3.1.7)

Ordering code rolling element assemblies

LWAKE9x13 ACS	LW	AKE	9	x	13	ACS	/	
Type								
JK	for LWRB							
AL, AK	for LWR							
AKE	for LWRE							
HV, HW	for LWRM/V and LWM/V							
Size								
1, 2	for LWJK							
3	for LWAK							
6, 9, 12	for LWAL							
3, 4, 6, 9	for LWAKE							
10, 15	for LWHV							
10, 15, 20, 25, 30	for LWHW							
Length								
Number of rolling elements for ball- and roller cages Length in mm for needle roller cages								
Anti-creeping system								
No code	without any ACS							
ACS	for LWAKE							
ACSM	for LWJK and LWAKE							
ACSZ	for LWHW							
Precision class								
No code	standard, as described in product tables							
G1	high (only available for needle roller cages)							

Ordering code special mounting screws

LWGD 9	LWGD	
Size¹⁾		
3, 4, 6, 9, 12, 2211	for all rails of the Modular Range and size 2211	
4020, 5025, 6035, 7040, 8050	for LWM/V	

Generally the same size as for the rail has to be entered.

¹⁾ Other sizes on request

Ordering code end pieces

LWERE 9

LW			/	
----	--	--	---	--

Type¹⁾

ERA for LWR / LWRB
ERB for LWR / LWRB
ERC with wiper for LWR

ERE for LWRE
EREC with wiper for LWRE

ERM for LWRM
ERV for LWRV
EARM with wiper for LWRM
EARV with wiper for LWRV

EM for LWM
EV for LVV
EAM with wiper for LWM
EAV with wiper for LVV

Size

1 ... 8050

Generally the same size as for the rail has to be entered.

Coating

No code standard, as described in product tables

HV chromed end pieces and screws

¹⁾ Take **table 2, Chapter 3.1.4**, in consideration

Ordering code precision rail guides in kit packaging

LW	RE	3	300	/	100	EG	ACS	-	KIT	/	z 10
----	----	---	-----	---	-----	----	-----	---	-----	---	------

Type

R
RE

Size

3, 6 for R
3, 4, 6 for RE

Rail length in mm (as defined in product tables) _____

Length of short rail in mm (optional, on request) _____

No code standard, four rails with the same rail length
Value two short rails with given length and lead in radius
and two normal rails

Anti-creeping system

No code without any ACS
ACS for LWRE 3, 4, 6
ACSM for LWRE 3, 6

Number of rolling elements z (optional, on request) _____

No code standard, as described in product tables
Value when other number of rolling elements is needed

Please complete the form with all available information and send it to your SKF representative or authorized distributor for product selection.

Application description

Specification sheet - Precision rail guide

Stroke	Rail length	Length of shorter rail	Distance B ₁	Distance B ₁ + A	Guiding system
mm	mm	mm	mm	mm	Maximum height mm
(† chapter 1.8.5)					<input checked="" type="radio"/> No constraints

Required service life distance or time (fill in all fields)

Distance	Total time	Period of one cycle	Stroke of one cycle	
km	h	s	mm	

Maximum speed¹⁾

Maximum acceleration¹⁾

m/s	m/s ²	N/ μm	μm
1) Here the maximum values. Enter load phase specific values in table "External loads and load phases"			Parallelism in height

¹⁾ Here the maximum values. Enter load phase specific values in table "External loads and load phases"

Environment

<p>Presence of dust, dirt or fluids</p> <ul style="list-style-type: none"> <input type="radio"/> Clean environment, e.g. laboratory <input type="radio"/> Standard industrial environment <input type="radio"/> Dirty environment, e.g. milling machine 	<p>Requirements on friction</p> <ul style="list-style-type: none"> <input type="radio"/> Lowest possible friction <input type="radio"/> Standard friction <input type="radio"/> No requirement
<p><input type="radio"/> Humid or corrosive environment</p> <p>If yes, please describe:</p>	<p>Preferred material</p> <ul style="list-style-type: none"> <input type="radio"/> No preference (standard) <input type="radio"/> Stainless steel <input type="radio"/> Coated steel

Temperature [°C]

Minimum	Operating	Maximum	<input type="radio"/> Shock loads or vibrations If yes, please describe:
---------	-----------	---------	---

Lubricant in use

Standard (SKF grease LGEP2) Other
Please specify:

Sketch of the application (or attach a drawing)

Product details**Rail designation (if already known)****Precision class of rail**

- P10 (Standard) P5 (Medium) P2 (High)

Designation of rolling element assembly (if already known)**Anti-creeping system needed** (recommended for high accelerations or vertical systems)

- Yes No

Needed accessories (for details see SKF publication 14259, Precision rail guides)

- End pieces Designation

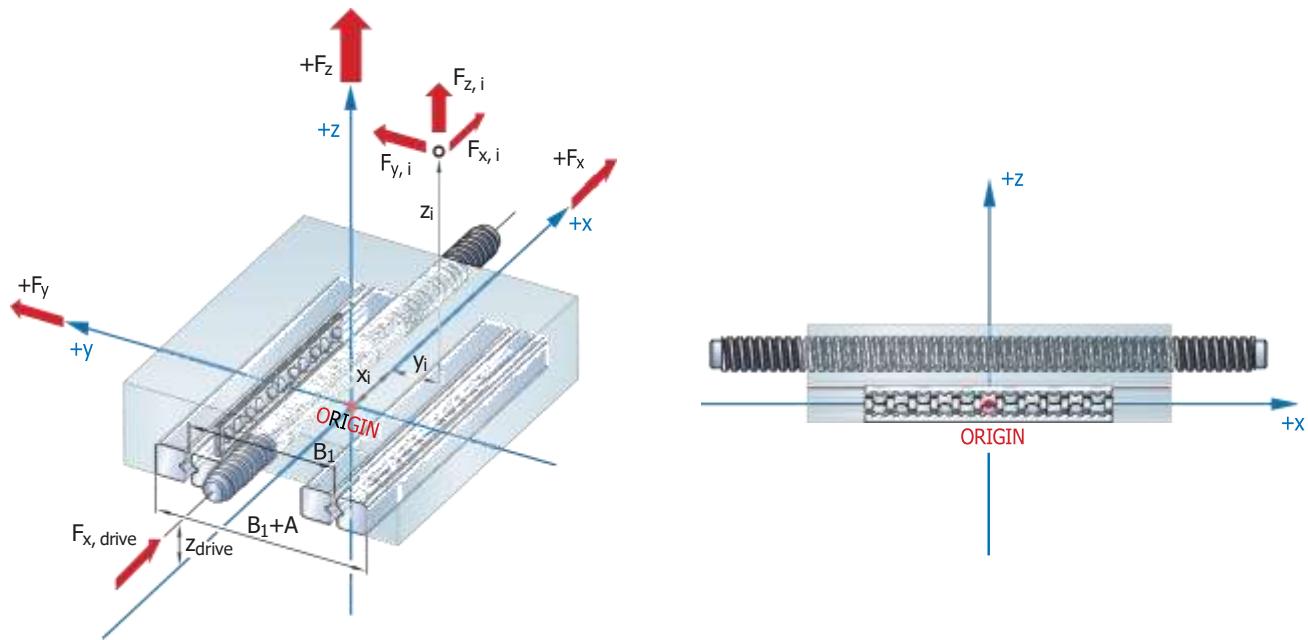

- End pieces with wipers
(requires long and short rails) Designation

- Special mounting screws – LWGD

Precision rail guides mounted into a complete system

- GCL GCLA System with drive, e.g. roller screw

Input for dimensioning calculation

Moving direction (set coordinate system accordingly)

Please specify:

- Horizontal
 - Vertical
 - Other

External loads and load phases

Forces in N, Lever arms in mm measured from defined origin (see graphcis above). If the application has more than 3 load phases, please copy this page.
